Summary

New Jersey Fish and Wildlife's Endangered and Nongame Species Program (ENSP) biologists, Conserve Wildlife Foundation (CWF) staff, and volunteer observers located and monitored bald eagle nests and territories. Two hundred sixty-seven nest sites were monitored during the nesting season, of which 250 were documented to be active (with eggs) and 17 were territorial or housekeeping pairs. Twenty-nine new eagle pairs were found this season, 14 in the south, ten in central, and five in the north. One hundred-ninety-seven nests (83%) of the 236 known-outcome nests produced 335 young, for a productivity rate of 1.42 young per active/known-outcome nest. Sixteen percent (39 nests) failed to produce young. The Delaware Bay region remained the state's eagle stronghold, with roughly half of all nests located in Cumberland and Salem counties and the bayside of Cape May County.

The state's eagle population would not be thriving without the efforts of the dedicated eagle project cooperators and volunteers who observe nests, report sightings, and help protect critical habitat.

Introduction

The records to document the abundance and distribution of eagle nests in New Jersey do not exist. In the 1930s-1950s, when local naturalists and birders began documenting bird activity, bald eagles had already been subject to persecution for decades because of their perceived predatory relationship to game and farm animals. One study supported by NJDFW in southern NJ indicated more than 20 pairs of nesting bald eagles in the Delaware Bay region of NJ in the 1950s (Holstrom 1985). As a result of the use of the pesticide dichloro-diphenyl-trichloroethane, commonly known as DDT, the number of nesting pairs of bald eagles in the state declined to only one by 1970 and remained there into the early 1980s. Use of DDT was banned in the United States in 1972. That ban, combined with restoration and management efforts by Fish and Wildlife's Endangered and Nongame Species Program (ENSP), resulted in population increases to 23 pairs by 2000, 48 pairs by 2005, 82 pairs by 2010, 150 pairs by 2015, and 220 by 2020. ENSP recovery efforts – implemented since the early 1980's – have resulted in a steady recovery as New Jersey's eagle population has rebounded from the edge of extirpation.

Recovery efforts were multifaceted. In 1982, after New Jersey's only remaining nest (located in Cumberland County's Bear Swamp) had failed at least six consecutive years, ENSP biologists removed the egg for artificial incubation at Patuxent Wildlife Research Center in Maryland, and after hatching, fostered the young nestling back to the nest. As a result of residual DDT contamination, the Bear Swamp eggs were too thin to withstand normal incubation. Artificial incubation and fostering chicks continued with success until 1989, when a new, younger female took over and the pair was able to hatch their own eggs.

Increasing the production from a single nest, however, was not enough to boost the state's population in a reasonable period of time. Mortality rates are high in young eagles (as high as 80%), and eagles do not reproduce until about five years of age. ENSP instituted a hacking project in 1983 that resulted in the release of 60 young eagles from Canada over an eight-year period (Niles et al. 1991). These eagles contributed to the increase in nesting pairs observed after 1990.

Bald eagles face many threats, with disturbance and habitat loss the greatest threats in our state. In addition, contaminants in the food web may negatively affect the eagles nesting in some areas of NJ.

Disturbance is defined as any human activity that causes eagles to change their normal behavior, and takes many forms, including mere presence of people in nesting or foraging areas. In general, people on foot evoke the strongest negative reaction (Buehler 2000). When eagles change their behavior in reaction to people, they cease doing what is best for their survival and the well-being of their eggs and young. Ultimately, that can reduce the survival of individuals and the population. ENSP biologists work to manage and reduce disturbance in eagle nest areas. A team of experienced volunteer observers, as well as education and safe viewing areas, are essential to this effort. Viewing eagles from safe distances, where eagles continue to act normally, is best for eagles and satisfies people's natural desire to see them. Biologists also protect habitat in a variety of ways, including working with landowners, identifying land for acquisition and management, and applying the state's land use regulations. ENSP has a history of investigating the impacts of organochlorines and heavy metals in eagles and other raptors nesting in the Delaware Bay region. Bald eagles, ospreys, and peregrine falcons nesting in the region have exhibited some reproductive impairment relative to other areas (Steidl et al. 1991, Clark et al. 1998), but more recent research indicates problems may be limited to very local areas of contamination (Clark et al. 2001). ENSP biologists collect samples that allow monitoring of contaminants in eagles during the nesting season, and monitoring nest success is an integral part of this research.

ENSP biologists, with the Division's Bureau of Law Enforcement staff and project volunteers, work year round to protect bald eagle nest sites. The competition for space in the most densely populated state in the nation makes it clear that critical habitat needs to be identified and, where possible, protected, to support a recovered bald eagle population. Critical habitat for eagles includes areas used for foraging, roosting and nesting, and is included in the program's Landscape Project mapping of critical wildlife habitats. Landscape Project mapping identifies suitable habitat that is associated with nests, foraging areas, and documented communal roosts.

The population of wintering bald eagles has grown along with the nesting population, especially in the last ten years. The NJ Eagle Project discontinued participation in the national Mid-winter eagle survey, but has conducted surveys to document important roosting areas in winter and year-round.

The federal government removed the bald eagle from its list of Endangered Species in August, 2007, in recognition of the national resurgence in the eagle population in the lower 48 states. The U.S. Fish and Wildlife Service oversees a 20-year monitoring period (through 2027) to watch for and investigate any problems that could compromise the eagle recovery. In addition, the Bald and Golden Eagle Protection Act remains in effect to protect nest and roost sites for bald eagles

nationwide. The bald eagle's official New Jersey status currently remains state-endangered for the breeding season and state-threatened for the non-breeding season, and state regulatory protection was unchanged by the federal action.

Objectives of the New Jersey bald eagle program:

- 1) monitor the recovery of the bald eagle in the state by documenting the status, distribution, and productivity of breeding bald eagles in NJ;
- 2) enhance nest success by protecting bald eagles and their nest sites;
- 3) monitor wintering areas and other concentration areas and plan for their protection;
- 4) document location data in the Biotics database and apply it to identify critical habitat using the Landscape Project mapping following mapping protocols;
- 5) provide information and guidance to landowners and managers with regard to bald eagles on their properties;
- 6) increase our understanding of bald eagle natural history in New Jersey as eagle repopulate habitats.

Methods

Nest Survey

All known nest sites are monitored January through July or through fledging. Volunteer nest monitors watch most nests from a distance of 1,000 feet, using binoculars and spotting scopes, for periods of two or more hours each week. Observers record all data including number of birds, courtship or nesting behaviors, incubation, feeding, and other parental care behaviors that provide essential information on nesting status. CWF staff contact volunteers weekly with an update and are available to discuss observer questions and data. Dates are recorded for incubation, hatching, banding, fledging, and, if applicable, nest failure. A nesting territory is considered "occupied" if a pair of eagles is observed in association with the nest and there is some evidence of recent nest maintenance. Nests are considered "active" if a bird is observed in an incubating position or if eggs or young are detected in the nest.

Observers report other bald eagle sightings to ENSP or CWF biologists, who review the information for clues to potential new nest locations. ENSP staff and volunteers investigate territorial bald eagles for possible nests through field observations. When evidence suggests a probable location, biologists may conduct ground or aerial surveys of the region to locate a nest. Following guidance from the US Fish and Wildlife Service's post-delisting monitoring plan (USFWS 2009), we maintain a list of occupied nests and territories for population monitoring. The list approach also supports the NJDEP's Land Resource Protection activities.

When necessary, nests are protected from disturbance with barriers or posted signs. Staff works in partnership with landowners and land managers to cooperatively protect nests. Nest monitors notify ENSP staff immediately if any unusual or threatening activities are seen around the nest site. The Division's Bureau of Law Enforcement conservation officers act to enforce protection measures as needed, and provide routine assistance as well.

At select sites, ENSP biologists enter the nest site to band young when nestlings are between five and eight weeks old. A biologist climbs the tree and places nestlings into a large duffel bag and lowers them, one at a time, to the ground. A team records measurements (bill depth and length, eighth primary length, tarsal width, and weight) and bands each eaglet with a federal band and a green state color band with an alpha-numeric code. A veterinarian examines each bird and takes a blood sample for analysis. Blood is collected and stored following techniques in Bowerman et al. (1994). Samples are stored frozen pending analysis by a technical lab. Nest trees are generally not climbed the first season to avoid associating disturbance with the new site.

Winter and Roost Surveys

In recent years, we in New Jersey did not participate in the National Mid-Winter Eagle survey held in January, finding that the standardized count no longer covered all important eagle areas. We have increased the efforts to document locations where eagles roost and otherwise concentrate in the winter months of January and February.

Results

Nest Survey

The statewide population rose to 267 territorial pairs in 2022, an increase of 20 from last year. We documented 250 pairs that were known active (meaning they laid eggs), an increase of 28 nests from 2021 (Figure 1); 17 pairs maintained nest territories but did not lay eggs. Eighty-three percent of nests, 197, were known to be successful in producing 335 young. The productivity rate for 236 known-outcome nests was 1.42 young per active nest, which is above the range of 0.9 to 1.1 young per nest for population maintenance. Sixteen percent of nests (39) nests failed to fledge young. We documented nest failures and brood loss that occurred: 369 chicks were reported in the nestling stage but only 335 were documented at fledging. The number of nestlings lost could be higher as monitors often cannot see the number of chicks in the first weeks after hatching.

Most nests were located in the southern portion of the state, particularly within 20 km of Delaware River and Bay (Figure 2). The majority of nests were located on private land, while the rest were on state, federal, county, and conservation-dedicated lands. Disturbance was an issue at many nests; posting and regular surveillance by staff and nest monitors remained essential to increase the chance of success.

All documented nests and significant dates of the nesting season are listed in Table 1. Excluded from the nest table were 64 previously documented nest sites that were unoccupied and where no new nest could be found, or search effort was lacking (Table 2).

Figure 1. Number of bald eagle nests and young fledged in New Jersey, 1990–2022. Blue bars=number of nests, and blue lines=number of young produced each year. In 2022, 250 pairs were active and 335 young were produced.

2022 Season Highlights

Telemetry

Endangered and Nongame Species Program biologists, with the Conserve Wildlife Foundation, have attached satellite transmitters on several eagle fledglings over the past six years. These tagged eagles are helping to identify eagle habitat and overnight roost areas by their activity patterns. Depending on funding, we will continue to use satellite tags on NJ eagles to help us understand habitat use and eagle distribution. In 2022 we followed one eagle. EagleTrax mapping shows the movements of all these eagles, and can be found on the Conserve Wildlife Foundation of NJ's [website, http://www.conservewildlifenj.org/protecting/eagle-trax/](http://www.conservewildlifenj.org/protecting/eagle-trax/)

Duke

We have been following “Duke” on NJ EagleTrax, since he fledged from the Duke Farms nest on June 15, 2019. He spent his first winter in the Chesapeake Bay region, and in March and April moved between NJ and PA, a pattern that continued through 2020. His second winter he ranged around Somerset County, often close to his natal site. During 2021 he moved between many of the same locations in MD, PA, and NJ. In his third winter of 2021-22 he ranged in the Somerset-Mercer area of NJ and Bucks Co, PA. His satellite tag did not transmit data 9/11-12/14/22 due to a battery failure, but surprisingly came back on and lasted until mid-April, when it stopped, possibly for good. This appeared to be a battery failure again, with no indication that Duke, himself, isn't still thriving in the wild.

Oran

On November 1, 2022 “Oran” was resighted in Stone Harbor, Cape May County, NJ by John Kauterman. He was banded on May 18, 2015, with NJ green band E/17 and outfitted with a transmitter, and named “Oran.” After fledging we were able to follow his movements on [NJ EagleTrax](#) as he moved around southern New Jersey, Maryland and took a trip up to Maine in 2016. In November 2016 his intact transmitter was found in a harvested corn field in Maryland. At the time we didn't know if he got the harness off or he died in that vicinity. Then on March 24, 2020, Oran was photographed in Port Mahon, Delaware, by Dwayne Ragin. At the time he was five years old and just reached maturity. The resighting in Cape May County in November was additional confirmation that he continues to do well, and, at seven years old, is likely to be in a nesting pair or looking to set up a territory.

Notable Efforts

For a third year, ENSP ran a “soft release site” in Dividing Creek, where we provided supplemental food (fish and road-killed mammals) to support young eagles separated from their parents, giving them a safe area where other eagles would provide the social learning they need. On July 8, a recent fledgling was found grounded in Neptune. The bird was released at the Dividing Creek site on August 10. Food was left daily for the first two weeks, then every 2-3 days, and trail cameras were used to document eagle use. The released eagle was not documented on trail cams in the following weeks, but two other, unbanded, juvenile eagles were seen. The release site was monitored until the end of August.

Potential Nest Sites

Biologists and observers actively searched for possible nesting eagles in several locations. The searches were in response to reports of eagles engaging in breeding behaviors. Areas that remain promising are Batsto Lake, Oswego Lake, Indian Mills Lake, Evesham, Flemington/Raritan River, White Lake, Musconetcong River and middle Delaware River, all of which have year-round eagle activity. In addition, several inland reservoirs in the north hold promise for eagle nesting.

Resightings of Banded Eagles

Resightings of NJ green-banded eagles have increased over the years, as have eagles seen in NJ that were banded in other states. In Table 3, we list the eagles resighted in recent years in our state and, in some cases, surrounding states. These resightings, accumulated with the help of many photographers and birders, provide insight into eagle movements during the years between fledging and settling into a territory, as well as adult birds at a nest site.

The list of resightings in Table 3 is ordered by the bird's identifier, primarily the color band code. For some individuals, we have multiple resightings that provide some history and a story of that bird's movements.

Table 3. Resightings of marked Bald Eagles in New Jersey and elsewhere, 2021-2022.

* Denotes a band that was resighted in previous years. Band code with a dash (-) has letter-number in line; code with a slash (/) has letter above the number.

Photos of some resighted eagles:

A-95 (origin 2002 Mannington Meadows) Observed 2/19/22 by J. Houston; known male in nesting pair at Heinz NWR. Found deceased 5/7/22 Cecil, MD, at age 20.

E/72 (origin Prospertown 2019) photographed in April 2022 in Bristol, PA, by D. Denner.

A-90 (origin Greenwich 2002) seen in April 2022 at Bombay Hook, DE, by J. Amende.

B-14 (hit by vehicle 9/14/21; rehabbed, banded & released 9/23/21) photographed at Dividing Creek in February 2022, by T. McGinty.

E/77 photographed 1/22/2022 at Forsythe NWR, by R. Nicol. Hatched in 2019, he was entering his 3-year-old (fourth calendar year) plumage.

Recoveries of Eagles in New Jersey

During this reporting period, 49 eagles were recovered, and of those, ten were treated and released. The remaining birds were found dead, died while in care, or were euthanized for these reasons: electrocution (8), impacts with vehicles (6), impact trauma (7); eagle-eagle combat (1); raptor attack (1) poisoning (1), lead toxicosis (1); Highly Pathogenic Avian Influenza (HPAI) (2), and unknown circumstances (11) (Table 4). Electrocution is a significant risk for bald eagles everywhere, because power distribution relies on smaller poles where “hot” wires are often positioned less than six feet distant where an eagle’s wingspan can result in wire connections. ENSP works with electric suppliers (Atlantic Electric, PSE&G, and JCP&L) to retrofit poles and mark lines where they are high risk, and we use data on eagle nests, roosts, and foraging areas to identify priority sites for those corrections. Among the eagles that died from undetermined cause, disease (like West Nile Virus) and lead exposure could be involved in deteriorated condition.

Table 4. Bald eagles recovered injured or found dead in this project year.

Date Found	Location Found	Facility	Origin	Age-Sex	Details
12/31/22	Centerton, Cumberland	NJDFW-Tuckahoe		AD-F	Found dead: vehicular impact
1/2/22	Southampton, Burlington	Mercer County		4.5y-M	Died 1/4; possible lead poisoning
1/8/22	Barneget area, Ocean	Toms River Avian		2-3y	Found injured; euthanized
1/12/22	Old Bridge, Middlesex	Raptor Trust		5y-M	Found injured, released 2/16 at Cheesequake banded B-20
1/14/22	Hopewell Twp, Cumberland	NJDFW-SRO			Electrocution
1/22/22	Upper Deerfield, Cumberland	Tri-State Bird Rescue		AD-F	Euthanized 1/22 due to old trauma
2/8/22	Quinton, Salem	NJDFW-Tuckahoe	Treated and released at TSBR 4/11/14	AD-M	Found dead as a result of eagle combat. Banded 0709-03526, when treated at TSBR in 2014 (hatched 2012).
2/14/22	Salem Co. Landfill	Tri-State Bird Rescue		AD-M	Released 3/8 banded B-16
2/24/22	Ridgefield Park, Bergen	Raptor Trust		AD-M	Released 3/23, banded B-21, lead poisoning via pellets. Blind in 1 eye.

Parks, Sandy Bonardi and Ken Habermann–Palisades Interstate Park Commission; NJ Meadowlands Commission staff; Kara Deutsch and Larry Hilaire–Delaware Water Gap National Recreation Area.

We thank Cape May County Department of Mosquito Control and New Jersey Forest Fire Service for aerial survey support. Special thanks to Fish & Wildlife Conservation Police Officers for protecting the state's eagles.

We are grateful to Dr. Erica Miller for expert veterinary support in the field and lab. Veterinary care was provided by these licensed wildlife rehabilitation centers: Tri-State Bird Rescue & Research, Mercer County Wildlife Center, The Raptor Trust, Toms River Avian Care, and the Avian Wildlife Center.

This project is funded by people who donate to the NJ Tax Check-Off for Wildlife and buy Conserve Wildlife license plates, and by the U.S. Fish and Wildlife Service's Wildlife and Sportfish Restoration Program

Little Egg Foundation provides the support for NestStory, the nest tracking program that allows real-time compilation of eagle nest data in NJ.
