SUMMARY

This report presents an evaluation of soil vapor intrusion into buildings located at Wall Township and Sea Girt Borough, Monmouth County, New Jersey. The evaluation has been completed as part of a research study titled "Investigation of Indoor Air Quality in Structures Located Above VOC-Contaminated Groundwater", which is being conducted by Golder Associates Inc. (Golder) for the New Jersey Department of Environmental Protection (NJDEP).

In 1997, elevated concentrations of tetrachloroethylene (PCE) were first measured in irrigation wells located in Wall Township and Sea Girt Borough. Subsequent testing of groundwater indicated a PCE plume in groundwater that covered an area approximately 1.5 miles wide and 2 miles long. The source of the PCE plume has been reported by NJDEP to be two former dry cleaner sites near State Route 35. The focus of this study is evaluation of soil vapor intrusion into houses located down-gradient from one of the sources, the White Swan dry cleaner site. Through analysis of groundwater, soil vapor and indoor air data, valuable information on soil vapor attenuation factors was obtained.

The buildings in the study area consist of small- to medium-sized residential dwellings with basements. The vadose zone soils consist of sand, and the depth to the water table is about 17 to 22 feet below ground surface. While there is uncertainty in PCE concentrations near to the surface of the water table, the near-water table PCE concentrations in groundwater range as high as approximately 400 μ g/L to 500 μ g/L below several houses. The PCE concentrations decrease in the down-gradient groundwater flow direction, and there is evidence for a fresh-water lens.

A comprehensive evaluation of groundwater, soil vapor and indoor air data for the Wall Township site indicates a positive relationship between groundwater and indoor air PCE concentrations. This trend, together with a spatial evaluation that indicates a pattern of elevated indoor PCE concentrations in houses above the highest groundwater concentration areas, provides evidence for soil vapor intrusion. In addition, the measured indoor air PCE concentrations in a number of houses were significantly above typical background levels for PCE published in the literature (US EPA, 2006).

The measured groundwater alpha's for PCE at the site range from approximately $1x10^{-6}$ to $1x10^{-3}$, although the maximum alpha values are uncertain. The filtered 90th percentile groundwater alpha $(8x10^{-4})$ is less than the alpha value that would be calculated for PCE using the NJDEP generic Groundwater Screening Level (GWSL) for the indoor inhalation pathway calculated for a contamination source at 1 m depth $(1.06x10^{-3})$. The 90th percentile alpha $(8x10^{-4})$ was similar to the predicted alpha $(8.27x10^{-4})$ calculated using the NJDEP generic GWSL defaults adjusted for a depth to groundwater of 3.2 m below the foundation level (i.e., the approximate depth to groundwater at the Wall Township site). The results of the study support the current generic GWSL in the NJDEP, which are not much higher than the 90th percentile level observed for this study.

The maximum filtered subslab alpha values for PCE were less than $1.3x10^{-2}$, with all but one data point less than $2.1x10^{-3}$. The filtered subslab alpha's were less than the default subslab alpha adopted by the NJDEP (2005) vapor intrusion guidance, which is $2x10^{-2}$.

The shallow external soil vapor concentrations were not considered suitable for calculation of alpha's since they were obtained at or above the level of the building foundation base. The external soil vapor concentrations were significantly less than those measured below the building, a trend also observed at other sites (Hers et al., 2006; Wertz 2006).

There is significant variability in the alpha factors for individual homes. The data analysis for groundwater alpha's suggested that the alpha's were significantly higher for houses with sumps, compared to houses without, and were also higher for houses located along Laurel Street, compared to those on Willow Road. The reason for the higher alpha value for houses on Laurel is not known, but may be related to closer proximity to the contamination source zone, geology and/or house construction.

ACKNOWLEDGEMENTS

We acknowledge the thoughtful input and guidance provided by Dr. Paul Sanders of NJDEP in completing this study, and the data compilation and information provided by Joe Marchesani, Laura Frederico and Robert Fowler of NJDEP. We also acknowledge the helpful review comments provided by Dr. Paul Johnson of Arizona State University.

1.0 INTRODUCTION

This report presents an evaluation of soil vapor intrusion into buildings located at Wall Township and Sea Girt Borough, Monmouth County, New Jersey. The evaluation has been completed as part of a research study titled "Investigation of Indoor Air Quality in Structures Located Above VOC-Contaminated Groundwater", which is being conducted by Golder Associates Inc. (Golder) for the New Jersey Department of Environmental Protection (NJDEP).

Elevated concentrations of tetrachloroethylene (PCE) were measured in 1997 in irrigation wells located in Wall Township and Sea Girt Borough. Subsequent testing of groundwater indicated a relatively large PCE plume in groundwater below a mostly residential area. The testing of indoor air quality in buildings located above the plume indicated elevated concentrations of PCE vapors in indoor air. Several phases of investigation, involving sampling and analysis of groundwater, soil vapor beside and below buildings, and indoor air, were completed at the site by NJDEP and US EPA.

The purpose of this study is to evaluate the degree to which soil vapor intrusion into buildings occurs and the processes and factors influencing vapor intrusion using the data available up to 2003. A key aspect of this work is to estimate vapor attenuation factors (indoor air concentration divided by the measured or predicted vapor concentration) for groundwater and subslab vapor sources. This analysis is valuable for comparison to generic factors incorporated in the New Jersey guidance for the soil vapor intrusion pathway (NJDEP, 2005).

Although there were two sources of PCE contamination at the site, the analysis of empirical data presented in this report is focused on buildings down-gradient of the White Swan dry cleaner site. An assessment of health risk was outside the scope of this study.

2.0 BACKGROUND INFORMATION

2.1 Overview

In 1997, the Monmouth County Health Department (MCHD) was notified that private well testing of several irrigation wells on Magnolia Avenue in Wall Township had shown elevated levels of tetrachloroethylene (PCE). Subsequent sampling of other private irrigation wells in the area by MCHD indicated widespread PCE contamination in shallow groundwater, as well as lower levels of trichloroethylene (TCE). The PCE concentrations in irrigation wells ranged from less the laboratory reporting (detection) limit to 1,648 ppb. Subsequent testing of groundwater indicated a PCE plume in groundwater that covered an area approximately 1.5 miles wide and 2 miles long.

Several follow-up investigations were completed by NJDEP and US EPA between 1998 and 2003 to evaluate the extent of chlorinated solvent contamination in groundwater, and to assess indoor air quality above the chlorinated solvent groundwater plume. As of June 2004, the indoor air quality in over 250 buildings had been tested. Subslab depressurization (SSD) mitigation systems were installed in most houses where indoor PCE concentrations exceeded 6 μ g/m3. Several rounds of post-mitigation testing of indoor air quality were subsequently completed.

Since the PCE concentrations in groundwater were present at concentrations that were much higher (one to three orders-of-magnitude) than breakdown products of PCE (e.g., TCE, cis-1,2-dichloroethylene, vinyl chloride), the main focus of evaluations at the Wall Township site was characterization of PCE.

2.2 Contamination Source Zone

There are two known sources of PCE contamination at the site consisting of the former White Swan dry cleaners (now a Fleet Bank) and the former Sun Cleaners site.

White Swan Cleaners, located at 1322 Sea Girt Avenue, Wall Township, New Jersey began operations in 1964. In 1983, the White Swan facility ceased to operate as a dry cleaner and began operations as a drop off and pick up point for dry cleaning performed off-site. Extensive on-site soil and groundwater PCE contamination was confirmed at the White Swan Cleaners. In December 2001, Fleet Bank excavated and disposed of about 820 cubic yards of on-site contaminated soil.

Sun Cleaners, located at 2213 State Route 35, Wall Township, is a defunct dry cleaning establishment that began operations in 1960 as Circle Dry Cleaning Corporation (Lockhead/REAC, 2002). In 1991, Sun Cleaners ceased to operate as a dry cleaner and began operations as a drop off and pick up point for dry cleaning performed off-site. As

of March 2002, the building was abandoned. An initial investigation at the dry cleaner site in 1996 indicated PCE concentrations in soil equal to 7,400 mg/kg (ppm) at six-foot depth and 4,400 ppm at 12-foot depth. A subsequent borehole investigation indicated PCE concentrations as high as 1,200 ppm in soil from 12 to 14 feet depth.

2.3 Site Description

The Wall Township site is located along state Route 35 in Wall Township, Monmouth County (Figure 1). The site extends from Route 35 eastward through Sea Girt Borough to the Atlantic Ocean. The northern limit of the site is hydraulically bounded by Hannabrand Brook. The southern limit of the site extends just south of Judas Creek (Figure 2).

The study area is situated in an essentially flat region of the New Jersey Coastal Physiographic province. The topography in the study area ranges from about 50 feet above sea level near Route 35 to sea level at the Atlantic Ocean. The natural topography in areas is altered slightly by human development, including the roads near Sun Cleaners, which were constructed on slightly raised embankments, and where existing streams were relocated.

Storm drains near Route 35 and Sea Girt Avenue discharge into Judas Creek. This creek acts like an intermittent stream that receives groundwater recharge to stream baseflow only during humid months of higher precipitation (usually in the spring season). There is a dam and gate to control sediment run-off on Judas Creek.

There are three groundwater pumping wells for municipal water supply located just east of State Route 71 (Figure 2).

2.4 Regional Geology

The study area is underlain by the unconsolidated sediments of Cretaceous and Tertiary age with an estimated total thickness of 1,600 feet. The unconsolidated formations generally strike northeast-southwesterly and dip to the southeast at an angle of 10 to 60 feet per mile. The near surface deposits consist of the Kirkwood-Cohansey Sands of the Miocene Epoch. The upper stratigraphic layer of this unit extends from ground surface to 50 feet below ground surface and consists of gravelly coarse to fine sands. The lower stratigraphic layer of the Kirkwood-Cohansey Sands consists of silty sands, sandy silts and trace to some clayey silt.

2.5 Hydrogeology

The Kirkwood-Cohansey Sands is a productive aquifer widely used for water supply purposes. It is predominantly under unconfined conditions and receives recharge directly from ground surface. As part of this review, no hydrogeologic test data for the site was available. However, test data for a nearby site (Waldic Aerospace site) indicates an upper stratigraphic unit hydraulic conductivity of $8x10^{-4}$ ft/sec and a lower stratigraphic unit hydraulic conductivity of $2.7x10^{-5}$ ft/sec. The average horizontal hydraulic gradient for both units was 0.005 ft/ft. Assuming an effective porosity of 0.33, an average linear groundwater velocity of 230 ft/year is calculated for the upper unit, based on the above parameters. Based on shallow and deep wells at the same location, the vertical gradients at the Waldic site range from approximately -0.05 ft/ft. downward in the summer months to 0.01 ft/ft upward in the spring months.

The depth to the water table down-gradient of the White Swan site is inferred to range from about 17 to 22 feet below ground surface based on observations during Geoprobe drive point installations.

3.0 GROUNDWATER QUALITY INVESTIGATION

The chlorinated solvent concentrations in groundwater were characterized through sampling of existing irrigation wells and other investigations where depth discrete groundwater samples were obtained using direct push Geoprobe technology. These groundwater investigations indicate that there are two dissolved PCE plumes in groundwater that originate from the contamination source area, which are the White Swan and Sun Cleaners site. The primary chemical of concern is PCE, with detectable TCE concentrations only measured in the immediate area of the source. The PCE concentrations in groundwater are shown on Figure 2, which is based on the following datasets:

- BEMSA White Swan Geoprobe Investigation (Samples 1 to 34): This investigation involved vertical profiling of PCE concentrations in groundwater using the Geoprobe method of sampling and was completed by March and October 1999. The shallowest groundwater sample was generally from between 17 and 20 feet, or 21 to 24 feet depth.
- "MAG" Series Geoprobe Investigation: This investigation was limited to collection of a shallow groundwater sample (21 and 24 feet or 22 and 24 feet) using the Geoprobe method. Since this investigation was conducted during a drought in July and August 2002, the water samples were reportedly obtained from near to the water table.
- MCHD Home Well Sample Results ("HW" series): These were irrigation wells that were sampled by the Monmouth County Health Department in the summer of 1998. The samples were obtained from varying depths. For this analysis, only PCE concentration from wells with recorded sample depths of less than 50 feet were used.
- **100-series samples**: These were limited to shallow groundwater samples obtained in April 2004 using the Geoprobe method of sampling.
- **BEMSA Sun Cleaners Investigation** (**GW-3 to GW-17**): This investigation involved vertical profiling of PCE concentrations in groundwater and was completed between January and September 2000. The shallowest groundwater sample was generally from between 16 and 20 feet, or 20 to 24 feet depth.

For completeness, the MCHD concentrations are included on Figure 2, although it is recognized that most samples were likely from screened intervals that were well below the water table. For the interpreted groundwater concentrations described below, the MCHD results were discounted and generally not used for contouring purposes.

The groundwater testing database is provided in Table 1. The maximum concentrations of chlorinated solvents were measured at Geoprobe samples obtained in the immediate vicinity of Sun Cleaners site. The maximum concentrations measured in groundwater were 15,500 μ g/L of PCE, 1,517 μ g/L of cis-1,2-dichloroethylene and 520 μ g/L of TCE were measured in the groundwater (Figure 2). The next highest concentration was measured a short distance down-gradient of the Sun Cleaners site (drive point sample GW-101) where 4,998 μ g/L of PCE, 658 μ g/L of cis-1,2-dichloroethylene and 244 μ g/L of TCE were measured in groundwater. The TCE concentrations in groundwater were considerably lower at other locations with the next highest measured concentration equal to 6.8 μ g/L.

The geoprobe investigations provided information on the vertical variation in groundwater concentrations. The vertical concentration profile at selected locations is shown in Figure 3. The groundwater samples were obtained over 2 to 3 foot depth intervals. As shown, at wells closer to the dry cleaner sources, the highest concentrations were obtained near the water table and concentrations generally decreased with increasing depth; in contrast, with increasing down-gradient distance from the source, the shallow groundwater concentrations were relatively low, and concentrations were highest at some distance below the water table. The vertical profile results indicates a sinking plume with the formation of a non-contaminated lens of water near the water table ("fresh-water lens) that increases in thickness with increasing down-gradient distance from the contamination source zone.

There are several sources of variability including well spacing, the depths over which the samples were collected, and different time periods over which samples were collected. As a result, there is a relatively high level of uncertainty in the PCE concentrations in shallow groundwater, which is of interest for evaluation of vapor intrusion. There were several wells where concentrations were lower than expected (e.g., #10 and #34 near the White Swan dry cleaner source) and others where the concentrations were greater than expected (e.g., HW-20). The uncertainty in shallow groundwater concentrations increases in the down-gradient direction and toward the edges of the plume. The estimated PCE (hand-drawn from visual interpolation) concentrations in shallow groundwater shown as concentration contours for the plume that originates from the White Swan source are shown on Figure 2. Again, it is important to emphasize the uncertainty in the delineation of the plume, particularly in the down-gradient direction. The dissolved plumes from the White Swan and Sun Cleaners sites likely co-mingle in the area of Laurel Street east of Old Mill Road.

The concentrations shown in Figure 2 were also contoured using the ArcGIS with Spatial Analyst extension (version 9.0) software contouring package, as shown on Figure 4. An Inverse Distance Weighted (IDW) interpolation routine was used for the contouring. The purpose of the contouring was to obtain an approximate visual representation of the spatial variation in groundwater concentrations. The anomalous contour results for the southwest area of the site on Figure 4 is due to lack of data. The concentration plot shown on Figure 4 was not used for estimation of groundwater concentrations for evaluation of vapor attenuation factors described below.

4.0 INDOOR AIR QUALITY INVESTIGATION

An initial investigation of indoor air quality was completed by NJDEP between approximately October 2001 and April 2002. The indoor air samples were obtained over 24 hours using Summa canisters and were analyzed according to USEPA Method TO-15. Prior to sampling, a detailed questionnaire and survey describing the building and use and storage of chemicals was completed by NJDEP. Subslab depressurization (SSD) mitigation systems were subsequently installed in most houses where indoor PCE concentrations exceeded 6 µg/m³. Several rounds of post-mitigation testing of indoor air quality were subsequently completed. The NJDEP indoor air quality data is provided in Table 2, Figure 5 and Appendix I. The three highest indoor PCE concentrations in air were measured at three nearby houses on Laurel Street (1,896 µg/m³, 223 µg/m³ and 156 μg/m³). The PCE concentration in the house where 1,896 μg/m³ was measured appears to be anomalously high since the indoor air concentration was almost one orderof-magnitude higher than other houses, and the groundwater alpha for this house was greater than 1x10⁻². The results for this house were not used for the vapor attenuation factor (alpha) analysis subsequently presented in this report.

A separate investigation of soil vapor and indoor air quality was completed by US EPA in early 2002. This investigation was limited to testing of soil vapor samples external to the building and/or subslab soil vapor samples, both obtained from a subset of the buildings. In most cases, indoor air samples were obtained concurrently with soil vapor sample collection. The external soil vapor samples were obtained at varying distances from the buildings at between 1.5 m and 2.6 m depth below ground surface. Since almost all houses had full basements, estimated to be about 2.1 m to 2.4 m below ground surface, the soil vapor samples were collected slightly below or up to 0.9 m above the elevation of the foundation. Subslab vapor samples were obtained within 0.3 m of the foundation slab. The soil vapor samples were obtained over a ½ hour duration using Summa canisters and analyzed using USEPA Method TO-15. Clay layers were noted at some locations during driving of probes. No other information on methodology for this investigation is available. The US EPA external soil vapor, subslab vapor and indoor air concentrations are provided in Table 3.

The indoor air, external soil vapor and subslab data, as well as estimated groundwater concentrations below houses within the White Swan study area are compiled in Table 4. The indoor air concentration is the best estimate concentration measured in the basement based on the combined NJDEP and USEPA datasets. For houses with multiple premitigation air measurements, the arithmetic mean concentration was calculated for testing conducted in late 2001 and early 2002. The groundwater concentration is the best estimate interpolated concentration based on the contours shown in Figure 2.

The indoor air concentrations measured at houses are shown in Figures 5 and 6. Similar to groundwater, the indoor air data was also contoured using the ArcGIS computer software (IDW interpolation routine) for visualization purposes, but was not used for analysis purposes (Figure 7). The external soil vapor and subslab vapor concentrations are shown on Figures 8 and 9, respectively.

The groundwater characterization programs were completed in summer 1998 (MCHD), spring to fall 1999 (BEMSA), and summer 2002 (MAG). While groundwater data collection was not concurrent with indoor air testing, the groundwater plume moves slowly and therefore non-concurrent testing likely does not represent a large source of error.

For many houses with elevated indoor PCE concentrations, multiple indoor air samples were tested both before and after the subslab depressurization system (SSD) was installed. The results, provided in Appendix II, indicate that indoor air concentrations decreased significantly after mitigation systems were installed, although for some houses, the PCE concentrations were still elevated for the first post-mitigation sampling event, and continued to decrease during subsequent monitoring events. The reduction in pre-and post-mitigation concentrations calculated using the final post-mitigation sampling round was generally between 60 and 90 percent (Table II-1, Appendix II). It is noted that some of the post-SSD air concentrations may be have been influenced by background sources of PCE. The monitoring data indicate that the SSD systems work reasonably well in reducing the indoor PCE concentrations.

The pre-mitigation air testing dataset, for buildings where multiple samples were obtained, also provide an opportunity to evaluate temporal variability in indoor air concentrations. The pre-mitigation air samples were generally obtained over a two- to six-month period. To characterize the indoor air variability, the relative percent difference (RPD) between the minimum and maximum concentration was calculated (i.e., (maximum-minimum)/average)), with results presented in Appendix II. The minimum and maximum RPD's were 24 and 188 percent, while the arithmetic mean RPD was 87 percent. It is not possible to evaluate possible seasonal trends since most data was obtained between December and March.

5.0 DESCRIPTION OF BUILDINGS IN VAPOR INTRUSION STUDY AREA

The buildings evaluated for this study were in almost all cases small- to medium- sized single family residences with basements. Two exceptions were 1316 Sea Girt (Garrison Autobody) and Sea Girt Lodge, which were commercial buildings that are believed to have slab-at-grade foundations. There were two houses with a partial basement and partial crawlspace (1310 Laurel and 2173 Old Mill Road). All buildings were described as having poured concrete floors with cinder concrete block walls, except 1200 and 1301 Sea Girt, where a partial dirt floor was observed. Several houses were observed to have sumps in the basement floor. The houses in this area are approximately 20 to 50 years old. The heating system for houses in this area are primarily forced-air furnaces supplied by natural gas. A detailed description of building characteristics is provided in Appendix III.

6.0 VAPOR ATTENUATION FACTOR ANALYSIS

The vapor attenuation factor (alpha) analysis consisted of calculation of three types of alpha's:

- Groundwater-to-indoor air ("groundwater alpha");
- Soil vapor-to-indoor air using shallow measurements external to the building ("soil vapor alpha"); and
- Subslab soil vapor-to-indoor air using subslab soil vapor measurements ("subslab alpha").

The measured alpha's were compared to regulatory alpha's incorporated in NJDEP (2005) and proposed USEPA (2006) guidance, different types of data were compared, and several factors potentially influencing the empirical alpha's were evaluated.

6.1 Groundwater Alpha

6.1.1 Overview of the Alpha Calculation Process

The groundwater-to-indoor alpha was calculated by dividing the measured indoor air concentration by the predicted vapor phase concentrations (derived from the interpolated groundwater concentrations in Figure 2) below each building. All buildings were residential single family dwellings. The measured indoor air concentrations were based on measurements in late 2001 and early 2002, and the estimated concentrations in groundwater were based on investigations completed between 1998 and 2002. The houses selected for alpha calculations were in areas where the PCE groundwater concentrations were greater than $80~\mu g/L$. This is because of the increased uncertainty in groundwater characterization near the edge of the plume. For statistical estimation of alpha, only data where groundwater concentrations exceeded 140 $\mu g/L$ were used, based on the rationale described below.

6.1.2 Filtering Criteria

The calculated groundwater alpha values were screened according to the data filtering criteria being developed for US EPA (2006) for empirical analysis of data, which is based on the concentration source strength. The filter discards data when there is a low potential that the indoor vapor concentrations will be greater than typical indoor background air concentrations, based on relatively conservative (high) estimates of the vapor attenuation factor. The tentatively proposed US EPA criteria for filtering groundwater data is as follows:

If $C_{vapor} < 10,000 * C_{background}$, then data is filtered

The source vapor concentration, C_{vapor} , is estimated from the groundwater concentration and the Henry's Law constant. The background concentration, $C_{background}$, is the 90th percentile of the literature background (6 $\mu g/m^3$) based on an unpublished evaluation of data for US EPA (2006). Several studies providing data on background indoor air concentrations are provided in NJDEP Vapor Intrusion Guidance (NJDEP, 2005). The reported median PCE concentrations for different studies ranged between 0.9 to 8.3 $\mu g/m^3$ while the 90th percentile concentrations were between 4 and 36 $\mu g/m^3$. The NYDOH (2005) report indoor air PCE concentrations that range between less than the detection limit (25th percentile) to 1.2 $\mu g/m^3$ (75th percentile).

The rationale for the 10,000X factor is that empirical data analysis completed for USEPA (2006) indicates that a filter based on an attenuation factor (AF) of $1x10^{-4}$ (1/10,000) was found to be sufficient to remove the confounding effect of background based on dilution factor that is at least 1,000 multiplied by additional 10X factor to further reduce the influence of background.

The groundwater concentration cut-off (140 μ g/L) based on the above filtering criteria was calculated as follows:

$$C_{gdw} = C_{background} * 10,000 / (H' UCF)$$
 [1]

where C_{gdw} is the PCE groundwater concentration ($\mu g/L$), H' is the temperature-adjusted Henry's Law constant (0.43) and UCF is a unit conversion factor (1,000 $\mu g/m^3/\mu g/L$).

6.1.3 Calculated Alpha's

The vapor concentration calculated from the measured or interpolated groundwater concentration (i.e., from Henry's Law constant) below each house versus the measured indoor air concentration is plotted in Figure 10. While there is considerable scatter in the data, there appears to be a trend indicating increasing indoor PCE concentrations with increasing soil vapor (groundwater) concentrations.

The calculated groundwater alpha's, shown in Figure 11, range from approximately $1x10^{-6}$ to $1x10^{-3}$. It should be recognized that the upper end of the alpha distribution may be populated with upwardly biased measurements due to uncertainty in the estimation of the groundwater concentrations below houses. Therefore, a statistical approach may be more appropriate for evaluation of alpha's, compared to one where the focus is on the maximum values. The 90th percentile of the alpha distribution may be a conservative, yet non-extreme value to account for possible errors and bias in the data.

The filtered 90th percentile alpha for data analyzed from the site is $8x10^{-4}$. For comparison, the alpha incorporated in the NJDEP Groundwater Screening Levels (GWSL's) for the vapor intrusion pathway is $1.06x10^{-3}$. The GWSLs's are calculated for a depth to vapor source of 1 m below the foundation. If the approximate depth (3.2 m) from the foundation to the vapor source (groundwater) is substituted in the GWSL calculation, then the predicted alpha $(8.27x10^{-4})$ is close to the measured 90th percentile alpha $(8x10^{-4})$.

A comparison of groundwater alpha's, for houses with and without sumps, is shown on Figure 12. Although, the data is limited, it appears that a sump may influence vapor intrusion based on the difference in the median alpha's, which were 2.6×10^{-4} for houses with sumps and 4.4×10^{-5} for houses without.

A comparison of groundwater alpha's houses on Laurel Avenue and Willow Road are shown on Figure 13. Based on the difference in the median alpha's, which were 1.6×10^{-4} for houses on Laurel Avenue and 2.8×10^{-5} for houses on Willow Road, there may be a difference in vapor intrusion characteristics for these two sets of houses. Most houses along Laurel Road included in this analysis were closer to the contamination source. As a consequence, the groundwater concentrations below these houses may have been underestimated resulting in an upward bias in the alpha factor. There may also be unknown factors relating to differences in the geologic conditions or foundation properties for the two areas of houses.

6.2 External Soil Vapor Alpha

The external soil vapor samples were obtained at or slightly above the foundation level and therefore are not considered suitable for prediction of indoor air concentrations. An in-progress assessment of soil vapor data for US EPA (2006) indicates that shallow external soil vapor data is unreliable for evaluation of soil vapor intrusion, and that deeper soil vapor data obtained from closer to the contamination source zone should be used. For example, there are several sites investigated in New York where shallow soil vapor concentrations in samples obtained at the foundation level were significantly less than subslab concentrations (Wertz, 2006; Anders, 2006). Shallow external soil vapor data tends to be highly variable and, in many cases, at lower concentrations than subslab data, due to soil disturbance, geological variability, differences between soil moisture below and adjacent to the building, and atmospheric pressure fluctuations. Shallow soil gas samples are also more prone to negative bias through short-circuiting of atmospheric air during soil gas sampling. A comparison of the PCE concentrations in shallow external soil vapor and subslab soil vapor samples indicates that in most cases the external concentrations were significantly lower than the subslab vapor concentrations (Figure 14).

Although there are limitations in this data set (Table 3), the external soil vapor concentrations were used to calculate soil vapor-to-indoor alpha's since this data is available and may provide some insight on soil vapor intrusion. The soil vapor alpha's calculated using the average soil vapor concentration measured adjacent to the building are shown in Figure 15, while the alpha's calculated using the maximum concentration (i.e., for multiple probes around a house) are shown in Figure 16. As shown, the soil vapor alpha's decrease with increasing source soil vapor concentrations. There are a number of possible reasons why alpha increases with decreasing source concentrations:

- In lower concentration areas (i.e., near the periphery of plume), there is greater lateral variability in soil vapor concentrations;
- As concentrations decrease, the background indoor PCE concentrations will have a proportionally greater influence on alpha; and,
- As concentrations decrease, the bias caused by possible dilution by ambient air during the soil gas collection process will increase.

While there are a number of individual points with attenuation factors that exceed the alpha incorporated in the NJ GWSL, it is important to emphasize that this shallow data should not be used for screening purposes.

6.3 Subslab Soil Vapor Alpha

The results of the subslab soil vapor-to-indoor alpha measurements (Table 3) are presented in Figure 17. The alpha was calculated by dividing the measured indoor air concentration by the measured subslab vapor concentration below each building. One subslab vapor sample per building was analyzed. All buildings were residential single family dwellings. The indoor air concentrations were from measurements in late 2001 and early 2002. The subslab vapor concentrations were based on investigations completed between 1998 and 2002.

The calculated subslab alpha values were screened according to the data filtering criteria being developed for US EPA, which is based on concentration source strength, as follows:

The maximum filtered subslab alpha values were less than 1.3×10^{-2} , with all but one data point less than 2.1×10^{-3} . The filtered subslab alpha's were less than the subslab vapor alpha adopted in the NJDEP (2005) vapor intrusion guidance, which is 2×10^{-2} .

7.0 SUMMARY AND CONCLUSIONS

There is a large dissolved PCE plume in groundwater that originates from two former dry cleaner sites in Wall Township. The focus of this study was to evaluate the potential for soil vapor intrusion into houses located down-gradient of one of the sources, the White Swan dry cleaner site. The buildings in the study area consist of small- to medium-sized residential dwellings with basements. The vadose zone soils consist of sand, and the depth the water table is about 17 to 22 feet below ground surface. While there is uncertainty in PCE concentrations in shallow groundwater just below the water table, the near-water table PCE concentrations range as high as 400 μ g/L to 500 μ g/L below several houses closest to the source. The shallow groundwater PCE concentrations decrease in the down-gradient groundwater flow direction, and there is evidence for a sinking plume with a fresh-water lens atop.

A comprehensive evaluation of groundwater, soil vapor and indoor air data for the Wall Township site indicates a positive relationship between groundwater and indoor air PCE concentrations. This trend, together with a spatial evaluation that indicates a pattern of elevated indoor PCE concentrations in houses above the highest groundwater concentration areas, provides evidence for soil vapor intrusion. In addition, the measured indoor PCE concentrations in a number of houses were significantly are above typical background levels for PCE published in the literature, as discussed in Section 6.1.

The measured groundwater alpha's at the site range from approximately $1x10^{-6}$ to $1x10^{-3}$, although the maximum alpha values are uncertain. The filtered 90th percentile groundwater alpha $(8x10^{-4})$ is less than the alpha value that would be calculated for PCE using the NJDEP generic GWSL for the indoor inhalation pathway calculated for a contamination source at 1 m depth $(1.06x10^{-3})$. The 90th percentile alpha $(8x10^{-4})$ was similar to the predicted alpha $(8.27x10^{-4})$ calculated using the NJDEP generic GWSL defaults adjusted for a depth to groundwater of 3.2 m below the foundation level (i.e., the approximate depth to groundwater at the Wall Township site).

The maximum filtered subslab alpha values were less than $1.3x10^{-2}$, with all but one data point less than $2.1x10^{-3}$. The filtered subslab alpha's were less than the default subslab alpha adopted by the NJDEP (2005) vapor intrusion guidance, which is $2x10^{-2}$.

The shallow external soil vapor concentrations were not considered suitable for calculation of alpha's since they were obtained at or above the level of the building foundation base. The external soil vapor concentrations were significantly less than those measured below the building, a trend also observed at other sites.

There is significant variability in the alpha factors for individual homes. The data analysis for groundwater alpha's suggested that the alpha's were significantly higher for houses with sumps, compared to houses without, and were also higher for houses located along Laurel Street, compared to those on Willow Road. The reason for the higher alpha value for houses on Laurel is not known, but may be related to closer proximity to the contamination source zone, geology and/or house construction.

		Subslab Alpha				Filtered	N/A

Note: The groundwater concentration is uncertain, this building does not appear to be above the PCE plume, but is close to the source. The indoor PCE concentration is anomolously high and the indoor air concentration is higher than the subslab concentration suggesting background indoor air source. Not considered reliable for for calculation of alpha.

Notes:

1. ND = Non detect. Detection limit equal to 3.38. When concentration below detection limit, detection limit used for calculation Min 59 2. The % reduction was calculated using the PCE concentration measured for the final post-mitigation round, Max 91 and the average pre-mitigation concentration. Average 79

APPENDIX III DESCRIPTION OF BUILDING CHARACTERISTICS

							# Floors						
x (State Plane Feet)	y (State Plane Feet)	Sump	SSD System Installed	Building Type	Basement Size	# Floors Below Grade	Above Grade	Foundation Type	Wall Construction	Floor construction	Heating	Dry Cleaning?	Other
614902	474748	Yes	2/11/2002	Residential	0.20	1	2	Cinder block	Cinder block	slab	9	2., 0.00g.	Paint odor, attached garage, strong gasoline odor garage
													Former sump filled in with concrete, pipes running through
618498	474118	No	5/23/2002			1.00	2		Cinder block		Natural gas, electric	Recently, but aired outside	walls/floor, solvents, paints stored in basement
616715	475038		12/5/2002	Residential		1	2	Cinder block		concrete floating?	Natural gas	No	
616461	475243	Yes	5/16/2002							<u> </u>	Natural gas	yes	Paint thinners, household cleaning products stored in basement
616485	475406			SFR		1	2	Cinder block		concrete floating?	Natural gas, wood	three days ago	Sump, paint thinner smell in basement
619147	474305	No	11/9/2002				2	Cinder block				, ,	
615905	474619		7 - 7			1.00	1	Cinder block		slab	natural gas		Paints, thinners stored basement
615692	474672					1.00	1	Cinder block		slab	natural gas		Paints, thinners stored basement
615538	474730				1000 ft	1 (8 ft ceiling)	1		Cinder block	slab, good condition	natural gas	1xmoth	Paints, thinners stored basement, pipes run through walls
615319	474611				18 by 22	(0/			Cinder block, good	slab	natural gas	2xmonth	walls
615256	474645				800 ft2	1.00	1	Cinder block	clinder block	slab	natural gas	no	Paints, thinners stored basement
						1 (1/2 basement,					8		
615406	474761	No				1 (1/2 basement, 1/2 crawlspace)	1				natural gas	1 to 2xmonth	
615327	474782	Yes	4/23/2002	SFR	1200 ft2	1/ 2 Clawispace)	1	Cinder block		concrete	natural gas	no no	Sump, heavy rain during sampling
615184	474663	Tes	4/23/2002	SFK	1200 112	1.00	1	Cinder block	sheet rock	slab	oil	no	paint, thinners basement
615267	474797	First Floor	4/16/2002		1000 ft2	1 (7 ft ceiling)	1	Cilidei block	SHEET TOCK	Tile	natural gas	twice a month	punt, uminers suscincin
615041	474696	Yes	4/ 10/ 2002		1000 112	1.00	1	Cinder block	Cinder block	slab	natural gas	2-3 weeks before sampling	paint, thinners basement
615152	474835	No	4/17/2002			1.00	1	Cinder block	cinder block	slab	natural gas	2x year	paint, thinners basement
615087	474854	No	5/15/2002			1.00	1	Cinder block	Cinder block	slab	natural gas	no	household cleaning products stored in basement
615032	474869	Yes	1/11/2002			1.00	2	Cirider block	Ciliaci biock	Sitto	natural gas	once month	paint, thinners basement
614839	474772	Yes	2/27/2002	SFR	800 ft2	1 full	2	Cinder block	cinder block, good condition	floating, good condition	natural gas	once month	paint, thinners, sump present basement
614772	474772	Yes	1/18/2002	Residential	000 112	1	2	Cinder block	Cinder block	floating	natural gas		solvents, gasoline stored basement, sump
614924	474915	No	2/15/2002	Residential		1	1	Cinder block	Cinder block	Slab	natural gas	every 2 months	paints, thinners, former sump, now sealed
614696	474817	Yes	1/7/2002			1	2	Cinder block	Cilidei block	floating	natural gas	once month	paint, thinners, household cleaning products in basement, sump
616789	474743	103	4/24/2002		900 ft2	1 (8 ft ceiling)		Cirider block	nov	v poured concrete over old cinder blo	Ü	once month	paints, thinners, solvent, glue, basement, UST beside house
616511	474848		4/ 24/ 2002	Residential	900 It2	1.00	1		Cinder block, good condition	slab, good condition	oil, natural gas	no	paints, thinners basement, UST
615751	474978		1/7/2003	SFR		full basement	2	Cinder blocks	Chidel block, good collation	Concrete	natural gas		No sump, heavy rain and wind during sampling on 10/16/02
615403	475114		1/7/2003	SFR		run basement	2	Concrete block		Concrete	natural gas		Sump, heavy rain and wind during sampling on 10/16/02
616715	476654	No		SFR		1	1	Cinder blocks		Concrete	Timurui Suo	3 months ago	No sump
3.37.10	555 1	110		0.11		partial basement, &		Direct Diocks		Concrete		o montho ugo	
615810	474858		5/22/2002			crawlspace			cinder block	slab	natural gas	Infrequently	solvents, paints, thinners stored basement
616583	473931	No	6/17/2002			1.00	3	Brick		Poured concrete, bare spots	natural gas	2 to 3 weeks	basement
616290	474044		12/6/2002	SFR		1 (full)				Concrete	natural gas	3 weeks ago	no sump
615445	474140		7.7-00-	SFR		1	2	brick		concrete and dirt	natural gas	no	no sump, old house
614947	474485			Residential	800 ft2	1 (8 ft ceiling)	1	Cinder block	Cinder block	concrete slab, good condition	natural gas	1 x month	Paints, thinners stored in basement
