### FINAL REPORT

## GEOLOGIC COMPONENT OF THE EARTHQUAKE LOSS ESTIMATION STUDY FOR MIDDLESEX COUNTY, NEW JERSEY

Prepared for the New Jersey State Police, Office of Emergency Management

by Scott D. Stanford, Ronald S. Pristas, David W. Hall, and Jeffrey S. Waldner New Jersey Geological Survey

## September 2003

**Summary:** Geologic, topographic, and test-boring data were acquired and analyzed in order to map seismic soil class, liquefaction susceptibility, and landslide susceptibility for Middlesex County (maps folded in pocket). The soil class, liquefaction susceptibility, and landslide susceptibility data were entered into the HAZUS model for each census tract in the county (Appendix A). The HAZUS model was run with the full upgraded geologic data and with the default geologic data for earthquake magnitudes of 5.5 and 6. To assess the effect of liquefaction, runs were also made with full upgraded geology and with upgrade without liquefaction for magnitudes 5, 5.5, 6, 6.5, and 7. Selected outputs from these runs are attached in Appendices B through M. The upgraded geology changed both the spatial distribution of damage and the total damage estimates compared to default geology. The upgraded geology produced greater building damage in the lower Raritan River valley and Arthur Kill areas of the county (Figure 1), where salt-marsh soils are softer and more liquefiable than the default, and less building damage in most other areas, where till, weathered-bedrock soils, and Cretaceous clay and sand are stronger than the default. Because most soils in the county are stronger than the default, the total economic loss is between 10 and 20% less with the upgraded geologic data than with the default data at all magnitudes. Adding liquefaction increases building damage about 10% in susceptible census tracts, especially at magnitudes less than 7, but results in less than a 5% increase in total loss for the entire county. This is a minimum value because the model does not calculate damage to roads, railways, and underground utilities caused by liquefaction. Structures that are particularly susceptible to damage from permanent ground displacement, such as pipelines and bridges, show significantly increased breakage when liquefaction is added.

In addition to the HAZUS data upgrades and runs, shear-wave velocity was measured on four soil types (Cretaceous clay, Cretaceous sand, Pensauken Formation sand and gravel, and stream-terrace sand) at a total of 12 locations. These measurements were made to check the soil-class assignments, which use test-drilling data as a proxy for shear-wave velocity. The measured velocities generally confirmed the assignments. Weathering reduces velocities in the near-surface parts of Cretaceous sand and clay, an effect previously observed in till in glaciated terrain.

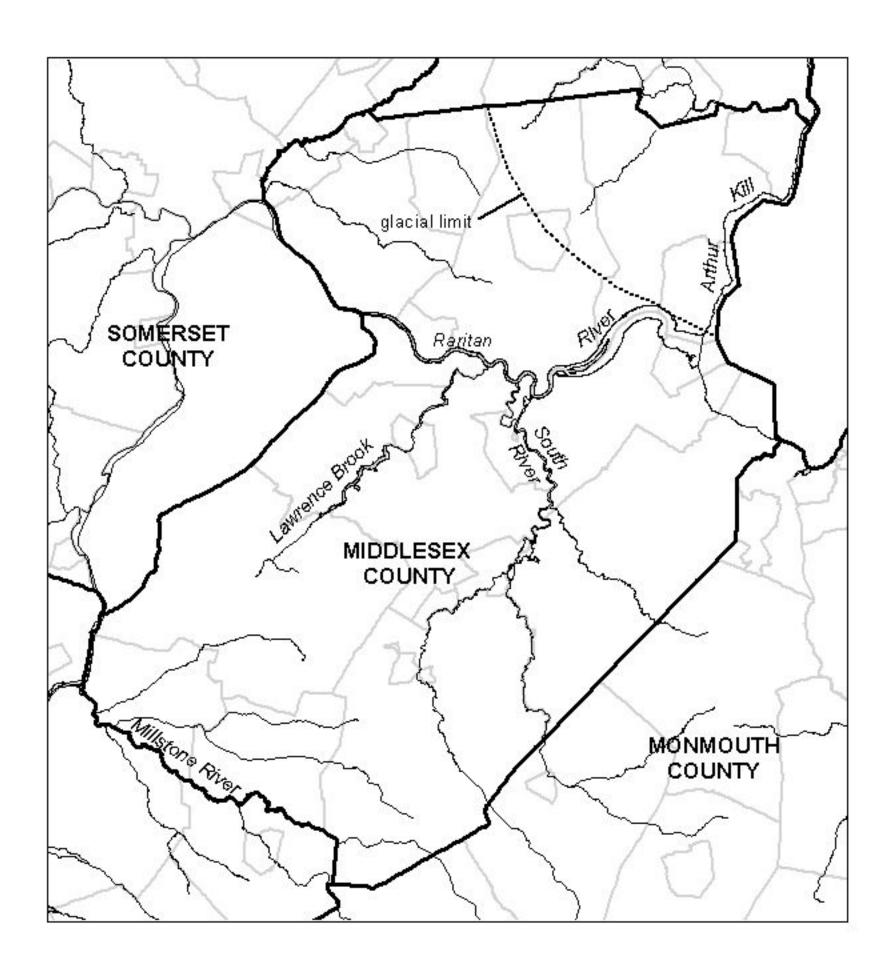

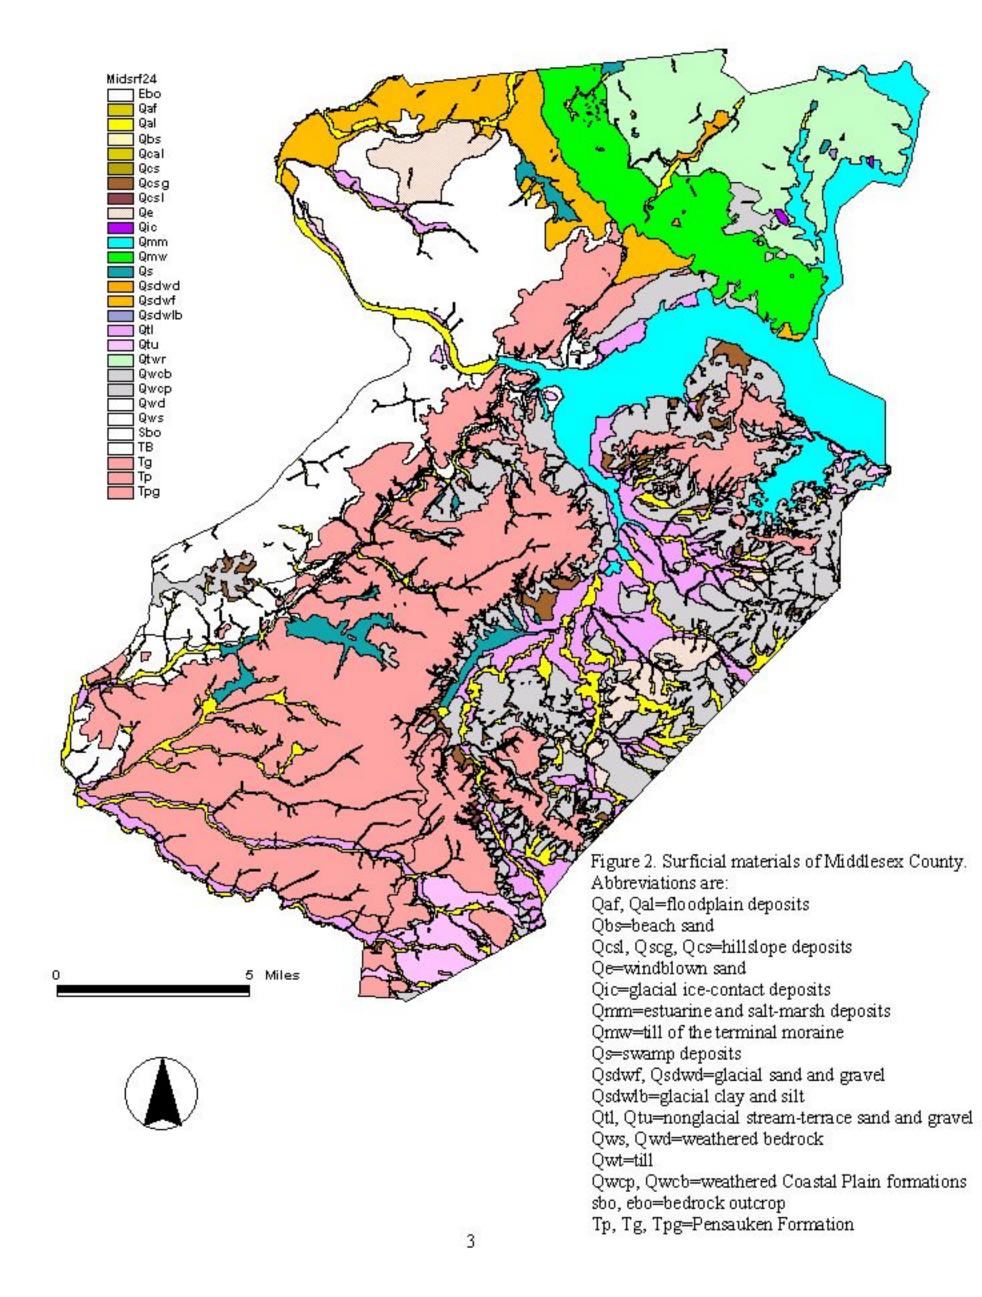

Figure 1. Middlesex County and vicinity. Gray lines are municipal boundaries.

Geologic Data Acquired: Twelve surficial materials were identified and mapped in Middlesex County (figs. 1 and 2). These include till, glacial-lake and glacial-river sand and gravel deposits, glacial-lake silt and clay deposits, postglacial floodplain deposits, peat and organic silt and clay deposited in wetlands, nonglacial stream-terrace sand, windblown sand, a preglacial river-plain deposit (the Pensauken Formation), weathered shale and diabase bedrock, and sand and clay of Cretaceous age. The distribution and thickness of these materials were mapped at 1:24,000 scale using stereo-airphoto interpretation, field observations, archival geologic map data on file at the NJGS, and logs of about 1200 test borings (Stanford, 1999).

Till is a compact silty sand to sandy silt with gravel and a few boulders, deposited directly beneath glacial ice. It veneers the bedrock surface in the northeastern corner of the county, northeast of the glacial limit (fig. 1), and is as much as 130 feet thick. Glacial-lake deposits overlie the till in the lowlands along the Arthur Kill and its tributaries. The lake deposits include sand and gravel as much as 30 feet thick and silt and clay as much as 20 feet thick. Glacial-river sand and gravel forms plains in the north-central and northwestern parts of the county. The glacial-river deposits are as much as 100 feet thick. Alluvial sediment was deposited in floodplains along all the main streams in the county after the glacier retreated. It is as much as 20 feet thick. Along Raritan Bay, the Arthur Kill, and the lower reaches of the Raritan and South Rivers, salt-marsh and estuarine deposits were laid down during postglacial rise of sea level. These deposits are as much as 100 feet thick. The extent of these deposits is important because they are loose, saturated soils that are especially susceptible to seismic shaking. Archival maps at the NJGS dating back to 1880 were used to delineate the original limit of the marshes, which are now covered by fill over much of their former extent.

Most of the county is beyond the limit of glaciation (fig. 1). Geologic materials in the unglaciated area include nonglacial and preglacial river deposits, weathered bedrock, and Cretaceous sand and clay. Nonglacial stream-terrace deposits of sand and pebble gravel border the floodplains of larger creeks. Sheets of windblown sand veneer uplands adjacent to some of these terraces. The terrace and windblown sands are generally less than 20 feet thick. A preglacial river-plain deposit of sand and gravel, the Pensauken Formation, covers much of the county south of the Raritan River, and is as much as 140 feet thick. Shale and diabase bedrock outcrop along the western edge of the county. The weathered soil mantle on these rocks is generally less than 10 feet thick. Cretaceous sand and clay of the Coastal Plain underlies the Pensauken Formation and stream-terrace deposits in the southern and southeastern part of the county. The Cretaceous deposits thicken to the southeast, to about 600 feet at the Monmouth County line.

**Data Analysis:** Shaking behavior and liquefaction susceptibility of soils are determined by their grain size, thickness, compaction, and degree of saturation. These properties, in turn, are determined by the geologic origin of the soils and their topographic position. Soils can be classed into the HAZUS categories using Standard Penetration Test (SPT) data, which are acquired during the drilling of test borings. SPT tests report the number of blows of a 140-pound hammer falling 30 inches that are required to drive a sampling tube 12 inches into the test material. Glacial and postglacial alluvial and wetland soils in Middlesex County are similar to those in Hudson, Essex, and Union counties, so the SPT data collected for the previous HAZUS studies

of those counties are also applicable to Middlesex County. These earlier data include approximately 300 borings in the Hudson County-Newark area, with a total of 4,777 SPT tests; 60 borings, with a total of 688 SPT tests, collected for western Essex County; and 193 borings, with a total of 944 SPT tests, collected for Union County. An additional 448 borings, with a total of 3528 SPT tests, were collected for Middlesex County (table 1). These additional data include tests in nonglacial stream-terrace deposits, weathered diabase, Cretaceous clay, Cretaceous sand, and Pensauken Formation, which are soil types that have not been previously investigated.

Table 1.--Standard Penetration Test (SPT) data for surficial materials in Middlesex County.

Material	Number of Borings	Number of Tests	Range of SPT Values	Mean ± Standard Deviation	Percentage of Zero Values	Percentage of Refusals (SPT>200)
fill	92	245	2-200	18±24	0%	1%
salt-marsh deposits	173	656	0-33	3±5	48%	0%
alluvial silt, sand, and clay	20	53	0-69	13±14	24%	0%
nonglacial stream-terrace sand and gravel	125	471	2-200	32±29	0%	1%
glacial-river sand and gravel	41	170	2-200	20±17	0%	0.6%
till	75	342	2-200	41±41	0%	3%
glacial-lake silt and clay	4	14	5-26	16±5	0%	0%
weathered shale	100	179	2-200	70±51	0%	3%
weathered diabase	57	119	16-200	75±45	0%	2%
Cretaceous clay	90	608	4-240	51±45	0%	3%
Cretaceous sand	95	465	4-316	57±51	0%	4%
Pensauken Formation sand and gravel	49	206	4-51	20±9	0%	0%

SPT data from the additional Middlesex County borings yield means and ranges similar to those from the Hudson, Essex, and Union data for the same soil types. Till in Middlesex County yields a somewhat lower mean penetration value than tills farther north (40 vs. 60-70). This reduction is due in part to thinner glacial ice in Middlesex County, which was at the

southern edge of the glacier. Thinner ice exerts less compaction pressure on the underlying till. Also, till in Middlesex County is less bouldery and cobbly than that farther north, reducing the number of penetration tests with high counts from encountering these hard objects.

For each surficial unit, a mean SPT value, and standard deviation, were calculated. This mean value is then applied to the mapped extent of the surficial unit to prepare the soil class map. Where more than one surficial material is present overlying bedrock, the appropriate mean SPT value is applied to the thickness of each layer. Fill includes a variety of materials ranging from demolition debris and excavated bedrock to trash and dredged silt and sand. Because of the variable composition of fill it is inappropriate to apply a mean SPT value, and fill was not included in the soil classification determinations. The behavior of fill under seismic shaking should be assessed on a site-specific basis. HAZUS soil classes were assigned according to the procedures described in sections 4.1.2.1, 4.1.2.2, and 4.1.2.3 of the 1997 National Earthquake Hazards Reduction Program (NEHRP) Provisions. These procedures assign a soil class by using a weighting formula to sum the soil and rock layers to a depth of 100 feet.

Liquefaction susceptibility was assigned based on Table 9.1 of the HAZUS Users Manual, with some modifications to the classification scheme based on local penetration-test data and field observations. For example, low compaction and penetration resistance of some saturated glacial-lake, glacial-river, and stream-terrace deposits of Pleistocene age indicate a moderate-to-high liquefaction susceptibility, rather than the low susceptibility for Pleistocene lake and river deposits provided in Table 9.1.

Landslide susceptibility depends on slope angle and the geologic material underlying the slope. Slope angles for Middlesex County were calculated from 1:24,000 topographic maps with 10- or 20-foot contour interval and slope materials were determined in the field. In places, particularly in the lower Raritan River valley, clay and sand mining operations and road construction have significantly changed the topography from that shown on the topographic maps. In these places, slope angles were estimated from aerial photography and field observations. Landslide susceptibility was assigned according to the classification in Table 9.2 of the HAZUS User's Manual (refer to map folded in pocket). Areas of potential landsliding include steep slopes on shale along the Raritan River and Lawrence Brook in the New Brunswick area, steep natural slopes in Cretaceous sand and clay, chiefly in the Cheesequake area along the southern shore of Raritan Bay, and faces of former sand and clay pits in the lower Raritan and South River valleys.

Shear-wave Velocity Measurements: To test the accuracy of using SPT data as a proxy for shear-wave velocity, and to collect data for soils lacking SPT tests, seismic data were collected at twelve sites in Middlesex County. The tested soil types include Cretaceous clay (3 sites), Cretaceous sand (3 sites), Pensauken Formation sand and gravel (3 sites), and stream-terrace sand (3 sites) (Table 2). The measurements were made at sites where the natural deposit was undisturbed and not covered or mixed with man-made fill. At each site, hand-auger holes were drilled to a depth of 5 feet to test for soil disturbance and fill. The seismic data were collected using a Bison 9000 digital engineering seismograph. Both shear wave (horizontal component) and compression (P) wave data were acquired (Appendix N). P-waves are much faster than shear waves and help in isolating the shear-wave signal in the seismic record. P-wave data generally show two velocity layers. The uppermost layer is unsaturated sediment and the lower

layer is saturated sediment. The boundary between the two layers is the water table. The water table is not detectable in shear wave data because liquids do not transmit shear waves.

Twelve shear geophones were used with a 6-foot spacing. The source was located 6 feet from the first geophone. Each geophone was oriented with its axis of movement parallel to the generating source. The source is a 6-inch channel steel beam that is 5 feet long and has triangular teeth welded to the bottom. A 10-pound sledgehammer is used to impact either side of the source. Two people stand on the source while it is being hit to improve ground coupling.

Compressional (P-wave) data were collected using the standard seismic refraction line type setup. Twelve 8-hertz geophones were used in-line at 6-foot spacing. A 10-pound sledgehammer and a strike plate are used as a source.

Table 2. Shear-wave velocity measurements. Complete data provided in Appendix N.

Site	Location (latitude; longitude)	Material	Measured shear-wave velocity (feet/second)	Shear-wave velocity range predicted from SPT data (feet/second)	Comments
New Road	40E21'46"; 74E33'02"	Pensauken Formation	1507	600-1200	faster than predicted due to clay hardening
Thompson Park	40E19'49"; 74E25'54"	Pensauken Formation	1998	600-1200	faster than predicted due to clay hardening
Pigeon Swamp	40E23'14"; 74E28'20"	Pensauken Formation	974	600-1200	agrees
Helmetta Boulevard	40E23'05"; 74E25'42"	Cretaceous sand	723 (layer 1) 2087 (layer 2)	1200-2500	agrees (layer 2)
Crescent Ave.	40E23'47"; 74E24'20"	Cretaceous sand	674 (layer 1) 1172 (layer 2)	1200-2500	slightly lower than predicted (layer 2)
Marlboro Road	40E21'51"; 74E19'19"	Cretaceous sand	638 (layer 1) 1799 (layer 2)	1200-2500	agrees (layer 2)
Texas Road	40E21'22"; 74E21'04"	Cretaceous clay	1252	1200-2500	agrees
Pension Road	40E20'10"; 74E21'22"	Cretaceous clay	768 (layer 1) 2122 (layer 2)	1200-2500	agrees (layer 2)
Old Bridge Golf Course	40E25'06"; 74E16'06"	Cretaceous clay	838 (layer 1) 1315 (layer 2)	1200-2500	agrees (layer 2)
Phillips Park	40E23'10"; 74E21'15"	stream-terrace sand	778 (layer 1) 1179 (layer 2)	600-1200	agrees

Jernee Mill Road	40E26'07"; 74E21'01"	stream-terrace sand	448 (layer 1) 632 (layer 2)	600-1200	agrees (layer 2)
River Road	40E32'12"; 74E29'59"	stream-terrace sand	771 (layer 1) 2857 (layer 2)	600-1200	agrees (layer 1; layer 2 is shale bedrock)

The first seismic break on the raw records from both the shear and compressional data is picked on the records much like picking first breaks for seismic refraction data. The regression velocity is calculated using the inverse slope on the time-distance curves. The data are also presented numerically as the interval velocity between consecutive geophones along each line and as an average of the interval velocities (Appendix N). This is done to check for lateral velocity variation along each seismic line. A large difference between the average velocity and the regression velocity is indicative of lateral hetereogeneities within the soil. The regression velocity is statistically more accurate as a bulk soil property.

Table 2 shows that 9 of the 12 tests yield velocities that fall within the range predicted from the county-wide SPT data for the layer in question. Seven of the nine measurements in Cretaceous sand, Cretaceous clay, and stream-terrace sand show an upper slow layer (layer 1). This layer, which is less than 5-10 feet thick, is material that has been decompacted by weathering, soil processes, and biologic activity such as root growth and animal burrowing. The faster velocities beneath this soil zone (layer 2) are better indicators of the compaction properties of the geologic material. The layer 2 velocities generally agree with the velocity range predicted from SPT data, which are acquired below the soil zone in most cases. At the River Road site, the stream-terrace deposit is about 10-15 feet thick over shale bedrock. Here, layer 1 is the velocity of the stream-terrace sand and layer 2 is the velocity of the shale bedrock.

Two of the three velocities measured in the Pensauken Formation are significantly faster than predicted from the SPT data. The Pensauken Formation is a feldspathic sand that weathers to form a clayey sand or sandy clay soil. When dry, the clay in the soil layer acts as a hardening agent and forms an upper layer of faster velocity than the formation itself. This fast layer masks the seismic signal from the slower material below. The Pigeon Swamp site is more poorly drained than the other two sites, and has a less-developed soil, so it does not have a dry, clay-hardened upper layer. The velocity measured here is likely more representative of the formation as a whole and falls within the range predicted from the SPT data.

**HAZUS Simulations:** To evaluate the effect of upgraded geology and liquefaction, a total of twelve simulations were run. Earthquake magnitudes of 5.5 and 6, with an epicenter at the county centroid (Appendix A) and a focal depth of 10 km, were simulated for both the default and the upgraded geology. Earthquake magnitudes of 5, 5.5, 6, 6.5, and 7, with the same epicenter and focal depth, were simulated for full upgraded geology and for upgraded geology without liquefaction. The selected magnitudes span the range of potential damaging earthquakes in the region. The largest local earthquake in historic records was an estimated magnitude 5.2 event in 1884 with an epicenter offshore from Brooklyn, and earthquakes with magnitudes between 6 and 7 have been recorded or estimated from historical accounts in South Carolina, the Boston area, southern Quebec, and the St. Lawrence Valley.

The geologic data were upgraded by modifying soil type, liquefaction susceptibility, and landslide susceptibility for each census tract using the seismic soil class, liquefaction susceptibility, and landslide susceptibility maps (folded in pocket). Many census tracts spanned two or more soil types. In these cases, the dominant soil under the most densely built part of the census tract was selected. Also, areas subject to landsliding cover only a small part of the census tracts that were assigned a landslide hazard. In these census tracts, however, highways and local roads, and some buildings, adjoin slopes that are landslide-prone, so the landslide hazard was judged significant. The default geology assigned a uniform soil type (class D), and no liquefaction or landslide susceptibility, for the entire county. Maps of the upgraded and default geology, by census tract, are provided in Appendix A.

Building damage best illustrates the effect of geology on the simulations, because it does not directly incorporate economic and demographic patterns. Appendices B through M provide tables showing the number of the buildings (classed by use) in various states of damage, and the probability of a given damage state for a given use class. The appendices also provide maps showing the percent moderate or greater building damage by census tract for the various simulations. The moderate-or-greater cutoff was used because buildings with moderate damage must be evacuated and inspected prior to reoccupancy. Thus, moderate damage requires significant population disruption and emergency response. A loss estimation sheet summarizing damage, economic loss, casualties, and population displacement for each HAZUS run is also provided. The total economic loss includes repair and replacement costs, contents damage, business inventory damage, relocation costs, capital-related income costs, wage loss, and rental loss. In order to assess the effect of liquefaction, tables showing damage to transportation and utility systems were also generated for each run.

Evaluation of Simulations: The upgraded geologic data produced increased damage estimates for census tracts on vulnerable soils in the lower Raritan River valley and Arthur Kill areas, and generally decreased damage estimates elsewhere, compared to the default data. This pattern reflects the softer salt-marsh soils along the lower Raritan and Arthur Kill, which are of less stable soil class and are more liquefiable than the default conditions, and the compact till, weathered rock, and Cretaceous clay and sand under much of the rest of the county. These soils are of stronger soil class than the default. Census tracts underlain by the vulnerable soils (classes D and E, with medium and high liquefaction susceptibility) show as much as 30% more buildings damaged to a moderate or greater state than the default (class D with no liquefaction susceptibility) damage. Census tracts underlain by compact soil (class C) show as much as 20% fewer buildings damaged than the default.

Because the area of the county underlain by compact soil is more extensive than the area underlain by vulnerable soils, the total number of buildings with moderate or greater damage is 30-40% less with the upgraded geologic data than with the default data, and the total economic and property loss is between 10 and 20% less with the upgraded geologic data (table 3). Note, however, that important transportation, waste-disposal, and industrial facilities are located in the vulnerable salt-marsh area, including segments of the Garden State Parkway and the New Jersey Turnpike, a powerplant, and several landfills, sewage treatment plants, refineries and oil terminals.

Table 3. Comparison of total economic loss (TEL, in billions of dollars), major building damage (MBD, in thousands of buildings), and displaced households (DH, actual number of households requiring shelter) for the HAZUS runs. Total economic loss includes building damage plus loss of building contents plus loss due to business interruption. Major building damage includes buildings of any type damaged to the "extensive" and "complete" state.

Magnitude		default			full upgrade	2	upgrade	without liq	uefaction
	TEL	MBD	DH	TEL	MBD	DH	TEL	MBD	DH
5.0	-	-	     -	0.5-1.9	<1	140-500	0.4-1.7	<1	40-150
5.5	1.5-6.2	2-8	1500-6000	1.3-5.2	1-6	1200-5000	1.2-4.9	1-5	1000-4000
6.0	3.2-13	6-30	6000- 22,000	2.9-11.5	5-20	5000- 19,000	2.8-11.2	5-20	4000- 18,000
6.5	-	-	-	5.1-20.3	11-50	10,000- 40,000	5-19.8	11-50	10,000- 38,000
7.0	-	-	-	7.7-30.6	20-80	17,000- 68,000	7.5-29.9	19-80	16,000- 65,000

Liquefaction accounts for less than 5% of countywide economic loss. However, census tracts with a moderate and high liquefaction susceptibility show as much as a 10% increase in the percentage of buildings damaged to a moderate or greater state, compared to no-liquefaction runs. More specific indicators of the effect of liquefaction are the performance of structures that are susceptible to damage from permanent ground displacement. Liquefaction, landsliding, and fault rupture (which is not a potential hazard in this area) cause permanent ground displacements, which are the principal cause of damage to gas, water, and sewer mains and other underground utilities, as well as damage to roads, railroads, and runways. Table 4 shows damage to bridges and table 5 shows damage to water and oil pipelines for each run. Note that water-line damage is proxied by households without water at day 1 following the earthquake, because HAZUS calculates loss of water service based on population, not from actual breaks and leaks in pipes. Outputs for road, railway, runway, and underground utility damage, other than the population proxy for water service, are not available, either because there is no default data (in the case of underground utilities) or because the software is not yet able to calculate the effect (in the case of road, railway, and runway damage).

Table 4. Comparison of bridge damage for HAZUS runs. Numbers indicate bridge segments (out of 936 total segments) damaged to the indicated state.

Magnitude	default		full up	full upgrade		upgrade without liquefaction	
	moderate	complete	moderate	complete	moderate	complete	
5.0	-	-	3	0	0	0	
5.5	36	2	38	3	26	1	
6.0	207	38	192	41	174	30	
6.5	-	-	392	136	375	116	
7.0	-	-	555	268	543	245	

Table 5. Comparison of water-main and oil-pipeline damage for HAZUS runs. "Households without water" is the number of households without water at day 1 after the earthquake, out of 238,974 total households in county. Number in parentheses is percentage of total households. Number of leaks or breaks for oil pipelines is out of 112 km of pipeline length.

Magnitude	e default full upgrade		default			upgrade	upgrade without liquefaction		
	households without water	oil pipeline leaks	oil pipeline breaks	households without water	oil pipeline leaks	oil pipeline breaks	households without water	oil pipeline leaks	oil pipeline breaks
5.0	-	-	-	0	0	0	0	0	0
5.5	0	2	0	24,234 (10%)	2	1	0	2	0
6.0	30,424 (13%)	10	2	129,570 (54%)	12	4	15,498 (6%)	10	2
6.5	-	-	-	196,616 (82%)	29	15	89,916 (38%)	28	10
7.0	-	-	-	226,245 (95%)	73	36	177,113 (74%)	62	16

Tables 4 and 5 show increases in damage to bridges and oil pipelines with the addition of liquefaction. There are 5 to 15% more pipeline breaks, 30 to 50% more pipeline leaks, and a 10 to 25% increase in completely damaged bridge segments, when liquefaction is added. The greatest impact is on water mains. Adding liquefaction increases the percentage of households without water from 0 to 10% at M 5.5, from 6 to 54% at M 6, from 38 to 82% at M 6.5, and from 74 to 95% at M 7. Similar results would be expected for gas mains. The combination of loss of water and rupture of gas mains creates increased fire hazard for structures on liquefiable soils.

The true impact of liquefaction is greater than indicated in these runs. As noted above, HAZUS did not calculate direct damage to underground utilities because there is no default data

for utility system lifelines. Upgrading the utility data would provide a more complete picture. Updated software that incorporates the effect of permanent ground displacements on roads, railways, and runways would also provide a more complete accounting.

### **Estimated Shelter Needs**

Type	Households	People
Displaced Households	140 - 500	
Public Shelter		80 - 300

#### Comments:

#### Disclaimer:

The estimates of social and economic impacts contained in this report were produced using HAZUS loss estimation methodology software which is based on current scientific and engineering knowledge. There are uncertainties inherent in any loss estimation technique. Therefore, there may be significant differences between the modeled results contained in this report and the actual social and economic losses following a specific earthquake. These results can be improved by using enhanced inventory, goetechnical, and observed ground motion data.

Level 4	Fatalities	20 - 80

#### **Estimated Shelter Needs**

Type	Households	People
Displaced Households	1,200 - 5,000	
Public Shelter		800 - 3,000

#### Comments:

#### Disclaimer:

The estimates of social and economic impacts contained in this report were produced using HAZUS loss estimation methodology software which is based on current scientific and engineering knowledge. There are uncertainties inherent in any loss estimation technique. Therefore, there may be significant differences between the modeled results contained in this report and the actual social and economic losses following a specific earthquake. These results can be improved by using enhanced inventory, goetechnical, and observed ground motion data.

# APPENDIX I

Magnitude 6 with upgraded geology, no liquefaction

Study Region: Middlesex County

Scenario Description: 6.0 Upgrade Scenario With Default Liquefaction

Percentage Of Buildings With Moderate and Greater Damage

Data from the HAZUS GIS software and the New Jersey Geological Survey. July 22, 2003

## **HAZUS99 SR-2 Loss Estimation**

### Estimated Economic Loss (S Billions)

Category	Description	Range
General	Building Damage	1.60 - 6.40
Building Stock	Building Contents	0.70 - 2.90
	Business Interruption	0.50 - 1.90
Infrastructure	Lifelines Damage	WIP.
The second secon	Total	2.80 - 11.20

### Estimated Building Damage(Thousands of Buildings)

Description	Residential	Commercial	Other	Total
Minor	40 - 160	1 - 4	< 1.0	40 - 170
Major	4 - 18	0 - 1	< 1.0	5 - 20
Total	50 - 180	1-5	< 1.0	50 - 190

### **Estimated Casualties: Day Time**

Severity Level	Description	# Persons
Level 1	Medical Aid	1,600 - 6,000
Level 2	Hospital Care	400 - 1,500
Level 3	Life-threatening	50 - 200
Level 4	Fatalities	100 - 400

### **Estimated Shelter Needs**

Type	Households	People
Displaced Households	4,000 - 18,000	
Public Shelter		3,000 - 11,000

#### Comments:

#### Disclaimer:

The estimates of social and economic impacts contained in this report were produced using HAZUS loss estimation methodology software which is based on current scientific and engineering knowledge. There are uncertainties inherent in any loss estimation technique. Therefore, there may be significant differences between the modeled results contained in this report and the actual social and economic losses following a specific earthquake. These results can be improved by using enhanced inventory, goetechnical, and observed ground motion data.

# APPENDIX K

Magnitude 6.5 with upgraded geology, no liquefaction

Study Region: Middlesex County

Scenario Description: 6.5 Upgrade Scenario With Default Liquefaction

Percentage Of Buildings With Moderate and Greater Damage

Data from the HAZUS GIS software and the New Jersey Geological Survey. July 22, 2003

## **HAZUS99 SR-2 Loss Estimation**

### Estimated Economic Loss (\$ Billions)

Category	Description	Range
General	Building Damage	2.90 - 11.50
Building Stock	Building Contents	1.20 - 4.70
	Business Interruption	0.90 - 3.70
Infrastructure	Lifelines Damage	
	Total	5.00 - 19.80

### Estimated Building Damage(Thousands of Buildings)

Description	Residential	Commercial	Other	Total
Minor	50 - 200	1 - 4	< 1.0	50 - 200
Major	10 - 40	0 - 2	< 1.0	11 - 50
Total	60 - 300	1 - 7	< 1.0	70 - 300

### **Estimated Casualties: Day Time**

Severity Level	Description	# Persons
Level 1	Medical Aid	4,000 - 15,000
Level 2	Hospital Care	1,000 - 4,000
Level 3	Life-threatening	140 - 600
Level 4	Fatalities	300 - 1,100

### **Estimated Shelter Needs**

Type	Households	People
Displaced Households	10,000 - 38,000	
Public Shelter		6,000 - 24,000

#### Comments:

#### Disclaimer:

The estimates of social and economic impacts contained in this report were produced using HAZUS loss estimation methodology software which is based on current scientific and engineering knowledge. There are uncertainties inherent in any loss estimation technique. Therefore, there may be significant differences between the modeled results contained in this report and the actual social and economic losses following a specific earthquake. These results can be improved by using enhanced inventory, goetechnical, and observed ground motion data.

### APPENDIX N

### Seismic velocity data

### Abbreviations are:

P-Wave=compressional wave
S-Wave=shear wave
gp spc = distance of geophone from source (feet)
pick = arrival time of wave at geophone (milliseconds)
int time = interval travel time between geophone (milliseconds)
int vel = interval velocity--wave velocity between geophones (feet/second)
avg vel = wave velocity calculated by averaging the interval velocities
regression velocity = wave velocity calculated from best-fit line to first arrivals
