Acronyms and Abbreviations

Term	Definition
Characterization Factor	A multiplier that converts resource use into a quantity of environmental impact.
Chemical Recycling	A process of recycling plastics by chemically breaking them down into their original monomers ¹ .
Cradle-to-Gate	An assessment of a partial product life cycle from resource extraction (cradle) to the factory gate (before it is transported to the consumer).
Dissolution	In the context of plastic recycling, dissolution is a process where a solvent is used to selectively dissolve the polymer from plastic waste. The method allows for the separation of the polymer from contaminants and other nontarget materials without breaking down the polymer's chemical structure ¹ .
Ecoinvent	The ecoinvent database is another life cycle inventory database that contains data on individual activities, similar to the U.S. Life Cycle Inventory database. It provides comprehensive data for life cycle assessments and is used globally.
End-of-Life Treatment	The final stage of a product's life cycle, involving disposal, recycling, or other forms of waste management.
Extrusion	In the context of plastic recycling, extrusion is a process where plastic waste is melted and reformed into new shapes.
Fischer–Tropsch Synthesis	A process that converts syngas into liquid hydrocarbons.
Gasification	In the context of plastic recycling, it is the process that breaks down plastic waste into gaseous fuels, or syngas, which can then be used to create new plastics.
Life Cycle Assessment	A technique to assess environmental impacts associated with all stages of a product's life from cradle-to-grave (i.e., from raw material extraction through materials processing, manufacture, distribution, use, repair and maintenance, and disposal or recycling).
Life Cycle Assessment Boundary	Defines the scope of a life cycle assessment study by specifying which processes and stages of a product's life cycle are included in the assessment.
Life Cycle Inventory	This involves compiling and quantifying inputs and outputs for a product system throughout its life cycle.
Mechanical Recycling	A process of recycling plastics by physically breaking them down into smaller pieces.
Methanolysis	A chemical process that breaks down polymers into monomers using methanol.
Monomer	A small molecule that can chemically bond with other identical molecules to form a larger molecule known as a polymer.
Operational Data	The quantitative inputs and outputs of a processes.

¹ Note - Dissolution is not considered a true chemical recycling technology because it typically does not involve breaking polymer bonds. However, it is often grouped with chemical recycling processes as dissolution relies heavily on chemical principles to understand polymer-solvent interactions, solvent selection, and solvent recovery (Vollmer et al. 2020).

Polymer	A substance composed of very large molecules, called macromolecules, which are made up of repeating structural units called monomers. These monomers are bonded together in long chains, giving polymers their unique properties.
Polymerized	The process of forming a polymer by bonding together multiple monomers.
Pyrolysis	A process of chemically decomposing organic materials at elevated temperatures in the absence of oxygen.
ReCiPe	A method for life cycle impact assessment that converts life cycle inventory results into a limited number of indicator scores.
SimaPro	A software tool used for life cycle assessment and sustainability analysis.
Syngas	A mixture of hydrogen, carbon monoxide, and some carbon dioxide, used as an intermediate in creating synthetic natural gas and producing ammonia or methanol.
U.S. Life Cycle Inventory Database	The U.S. Life Cycle Inventory database is a life cycle inventory database that contains data on individual activities, such as the transportation of materials. The U.S. Life Cycle Inventory database is more focused on the United States compared to ecoinvent.
Virgin Plastic Production	The production of new plastic materials from raw materials, rather than recycled materials.

Executive Summary

This Life Cycle Assessment (LCA) report, commissioned by the New Jersey Department of Environmental Protection (NJDEP), evaluates the environmental impacts of producing plastic through six different methods: virgin production, mechanical recycling, and four chemical recycling technologies (pyrolysis, gasification, methanolysis, and dissolution). The study focuses on three major plastic types—polypropylene (PP), polystyrene (PS), and polyethylene terephthalate (PET)—selected because they were optimally fit for the chemical recycling technologies and corresponding outputs chosen for this study. These plastic types also had overlap between scenarios which facilitated comparison of recycling technologies per plastic type.

ES 1.0 Scope and Approach

- **Functional Unit:** The analysis is based on the production of 1 kg of plastic ready for use in manufacturing.
- **System Boundaries:** The study uses a cradle-to-gate approach, assessing impacts from raw material extraction or waste collection up to the point the plastic leaves the manufacturing/recycling facility. Use, transport, and disposal of finished products are excluded.
- **Scenarios Modeled:**
 1. **Virgin Production:** PP, PS, PET from fossil feedstocks.
 2. **Mechanical Recycling:** PP, PET from post-consumer waste.
 3. **Pyrolysis:** PP via thermal decomposition.
 4. **Gasification:** PP via syngas and Fischer–Tropsch synthesis.
 5. **Methanolysis:** PET via chemical depolymerization.
 6. **Dissolution:** PP, PS via solvent-based recovery.

ES 2.0 Methodology

- **Modeling Tool:** SimaPro Craft (v10.2.0.0) was used for scenario modeling.
- **Impact Assessment:** The ReCiPe 2016 method was applied, which defines 18 midpoint categories. For clarity and relevance, the results in this report focus on 6 midpoint categories: global warming, stratospheric ozone depletion, ozone formation (human health/terrestrial ecosystems), terrestrial acidification, freshwater eutrophication, and marine eutrophication. Supplemental information is provided in the final presentation material.
- **Data Sources:** Operational data were drawn from peer-reviewed literature, industry reports, and databases (Ecoinvent v3.11, USLCI+ v1.2024-10.0), with prioritization of U.S.-specific data where available.
- **Allocation:** Mass allocation was used to distribute impacts among coproducts.

- **Local Policy Compliance:** This assessment does not evaluate compliance with New Jersey's Recycled Content Law (N.J.S.A. 13:1E-99.135 et seq.). The system boundary is designed to evaluate environmental impacts associated with polymer recovery via advanced recycling, rather than the production of post-consumer recycled content as defined under New Jersey statute.

ES 3.0 Key Findings

- **Virgin Production** has high impacts on global warming, ozone formation, and acidification due to fossil feedstock extraction and energy-intensive processing.
- **Mechanical recycling** of polypropylene (PP) and polyethylene terephthalate (PET) generally yielded the lowest environmental impacts for most impact categories.
- **Pyrolysis** of PP is the second highest for all impact categories, except for acidification, where it is the third highest behind gasification and virgin production. This is mainly due to the steam cracking step having large upstream environmental loads and the emissions produced from this step.
- **Gasification** of PP was identified as the scenario with the largest impacts across all categories. Gasification has numerous energy-intensive steps (gasification, cleaning of gases, F-T synthesis, cracking), and a variety of chemical compounds. Each of these steps adds complexity and increases the environmental footprint because more resources are consumed resulting in greater impacts.
- **Methanolysis** of PET had the highest impacts across most impact categories for PET (compared to virgin plastic production and mechanical recycling), primarily due to high energy and cooling demands in the crystallization and purification steps.
- **Dissolution** of PP and PS resulted in intermediate impacts—higher than mechanical recycling but lower than pyrolysis or gasification—driven by solvent and antisolvent use, as well as energy for dissolution and precipitation. This process is more energy- and resource-intensive than mechanical recycling.
- **Process Hotspots:** The washing step in mechanical recycling is a major contributor to environmental burdens. In chemical recycling, crystallization (methanolysis) and dissolution reactors are dominant impact drivers due to cooling, solvent use, and upstream supply chain emissions. Gasification and pyrolysis impacts are driven by energy, steam, and chemical inputs needed for these recycling methods.

ES 4.0 Sensitivity Analyses

- **Electricity Source:** Impact results are highly sensitive to the choice of electricity characterization factor (USLCI+ vs. Ecoinvent) for water consumption.
- **Pyrolysis Feedstock Substitution Rate:** Higher substitution rates of pyrolysis oil in steam cracking with the inclusion of a purification step before the steam cracking increases overall impacts, highlighting the importance of feedstock composition.
- **Pyrolysis Purification:** Removal of the purification step in pyrolysis decreases impacts due to the lowered resource and energy requirements.

ES 5.0 Study Context and Data Gaps

This initial study was conducted using the best available data from a thorough literature review and ongoing discussions with NJDEP. The primary objective was to develop preliminary estimates of environmental impacts for various plastic recycling and production scenarios, while also identifying critical data gaps that limit the conclusiveness and realism of the results.

Several gaps were identified—including the lack of direct, New Jersey-specific operational data, and uncertainties in energy and material flows. As such, this study may be viewed as a foundation for future work: it offers initial insights and, more importantly, highlights where targeted data collection and methodological refinement are needed.

This study developed a framework to apply primary data in the future. Thus, addressing these gaps will enable NJDEP to conduct a more robust and realistic assessment in subsequent studies, supporting better-informed decisions for policy and program development.

ES 6.0 Recommendations and Next Steps

- **Data Collection:** Obtain direct operational data from New Jersey recycling facilities to improve accuracy.
- **Functional Unit Evaluation:** Consider alternative functional units and expanded boundaries to capture broader impacts.
- **Process-Specific Data:** Refine energy and material flow data for individual steps.
- **Material Circularity Metrics:** Incorporate polymer quality retention and circularity in future assessments as it may provide a more complete picture of long-term sustainability.
- **Regular Updates:** Repeat LCA studies periodically to reflect technological and electrical grid energy mix changes.
- **Policy Specific Scenario:** A policy-aligned scenario designed to meet New Jersey's Recycled Content Law would require different feedstock specifications and product quality constraints, likely increasing reliance on virgin polymer and mechanical or dissolution recycling. Such changes would alter impact profiles relative to the advanced recycling pathway evaluated here.

ES 7.0 Intended Use

This study is an informational life cycle assessment conducted independently of any regulatory or policy mandate and is not intended to be solely relied upon for decision making. It was not developed to fulfill specific regulatory requirements or policy standards. Further study refinement, including resolution of identified data gaps, should be conducted if results of this study are used as the sole source for decision making.

1.0 Introduction

1.1 Project Background

Plastic products are typically produced using plastic made from hydrocarbons (i.e., coal, oil, and natural gas). Alternatively, plastic waste can be used to manufacture new plastic products through mechanical or chemical recycling. Mechanical recycling processes plastic waste without altering its molecular structure while most chemical recycling reduces plastic waste into its chemical building blocks.

Dissolution, is recognized in peer-reviewed literature as a unique subset of chemical recycling - distinct from thermochemical and solvolysis approaches. It uses solid-liquid extraction and solvent purification. Unlike depolymerization, dissolution retains the polymeric structure of the plastic. Mechanical recycling has been a commercial practice since the late 1980s, enabled by enhanced sorting of plastics during that time frame. Chemical recycling gained traction later, with the awareness of mechanical recycling limits, technological advances, deregulation of solid waste processes, and recycled content mandates, driving its commercialization by approximately 2015. However, the viability of chemical recycling remains contested due to its resource intensity, environmental trade-offs, and efficacy to recycle as plastic-to-plastic. The scientific literature assessing the methods of producing plastic by the mechanical and chemical recycling technologies is diverse with inconsistent findings.

A November 2024 assembly statement to the State of New Jersey stated that New Jersey's post-consumer plastics recycling rates are approximately 6-9% with some calculations suggesting as much as 13% (Assembly Environment, Natural Resources, and Solid Waste Committee, 2024). With the regulations around transboundary shipments of plastic waste becoming more strenuous, recycling methods continue to be assessed as alternatives for managing plastic waste for the production of plastic products. Thus, it is increasingly important to understand the environmental implications of the plastic-to-plastic recycling methods. Building this understanding is an important step to informing decision makers like policymakers and industry stakeholders on the optimal methods, major factors, and limitations for producing plastic by these methods.

1.2 Study Objective

The New Jersey Department of Environmental Protection (NJDEP) commissioned this study to compare the environmental impacts of using mechanical recycling, chemical recycling, and virgin materials to produce plastic. This study will also be used to identify areas for a future analysis by highlighting data gaps, areas of uncertainty, and anomalies in the results.

Major project activities that have already been completed as a part of this project are:

- Performed a literature review, which defined recycling processes
- Development of a quality assurance project plan (QAPP) which outlined the scope and quality practices of this study
- Development of a life cycle inventory (LCI) which collated the operational data used for this study

- Development of an LCI letter which described data gaps and major assumptions in the life cycle inventory
- Development of an LCIA Memo which summarized the results of the modeling

These project activities were separate deliverables. While they were used to inform this report, they are not included in this final report.

2.0 Scope and Methodology

The sections that follow describe the scope, modeling scenarios, system boundaries, methodology used, and deviations from the Quality Assurance Project Plan (QAPP) used in this study.

2.1 Scope

The cradle-to-gate analysis (i.e., from raw material extraction to the point the product leaves the factory as a pellet/flake before product manufacturing) evaluates six methods—called “scenarios” herein—for producing 1 kilogram (kg) of plastic. The scenarios include one or more of the following plastic types: polypropylene (PP), polystyrene (PS), and polyethylene terephthalate (PET). These three plastic types were selected because they were optimally fit for the chemical recycling technologies and corresponding outputs chosen for this study. These plastic types also had overlap between scenarios which facilitated comparison of recycling technologies per plastic type. The scenarios address conventional manufacturing, mechanical recycling, and four types of chemical recycling:

- **Virgin Material Production (Scenario 1):** Production of PP, PS, and PET plastic using virgin materials
- **Mechanical Recycling (Scenario 2):** Production of PP and PET plastic using mechanical recycling of post-consumer plastic waste
- **Pyrolysis (Scenario 3):** Production of PP plastic using pyrolysis of plastic waste
- **Gasification (Scenario 4):** Production of PP plastic using gasification of plastic waste
- **Methanolysis (Scenario 5):** Production of PET plastic using methanolysis of plastic waste
- **Dissolution (Scenario 6):** Production of PP and PS plastic using dissolution of plastic waste

An assessment of the life cycle environmental impacts of each plastic production scenario has been modeled, and the results are presented in this report. The detailed life cycle inventory data supporting this analysis are provided in **Appendix A**. Elements of material circularity are not included in this analysis, but considerations are discussed in **Appendix B**.

Functional Unit: The functional unit is 1 kg of plastic that is ready for use in a product manufacturing process.

2.1.1 System Boundaries

The system boundary of an LCA defines which processes are considered within the scope of the study, and thus what is included in (and excluded from) the analysis.

The cradle-to-gate system boundaries for this LCA study were developed based on a review of scientific literature and assumptions agreed upon with NJDEP. A table of the scientific literature reviewed can be found in Section 3-1 Literature Sources.

Scenario 1 (production of plastic from virgin materials): Scenario 1 models the production of virgin plastic. Virgin plastic production encompasses impacts from fossil feedstock extraction, monomer synthesis, and polymerization (the characterization factor does not specify if extrusion is included).

This scenario starts with the extraction of virgin materials and ends with the production of plastic for use in manufacturing. All steps after the production of the plastic (i.e., manufacturing plastic into a product, transporting the product, use of the product, eventual disposal of the product) are considered to be outside the scope of this study.

Scenarios 2 to 6 (production of plastic from mechanical and chemical recycling): A cradle-to-gate approach is used to assess the recycling technologies from the waste generation location (i.e., curbside collection) to the materials recovery facility (MRF) for sorting to generate the plastic bale, and then through the recycling processes. The recycling processes include transport to the recycling facility, pretreatment processes, recycling process steps, and extrusion into pellets. The recycling scenarios do not include transport and resale of by-products (the impacts of by-products of the recycling processes are excluded from the results by way of mass allocation), but do include impacts from process waste (e.g., emissions made directly into the atmosphere, wastewater).

These scenarios start with the collection of the plastic waste at the waste generation site (i.e., a centroid location representing the collection of plastic waste from homes and businesses) and ends with the production of plastic for use in manufacturing. The plastic waste is considered to be burden-free for the recycler, meaning the recycler is not responsible for the impact of the original creation of the plastic or its use. These recycling scenarios are based on single stream-recycling where the plastics are collected commingled with other plastic types and other recyclable Class A materials. Energy impacts from sorting out each of the plastic types are accounted for in the waste sorting process steps. The management of contamination, the non-plastic material separated from the plastic stream that is ultimately landfilled or incinerated, (e.g., the energy and environmental impacts from managing PP waste removed from a primarily PS stream) is not accounted for.

All Scenarios: Comparative LCA studies sometimes apply a differential (incremental) modeling approach, whereby processes that are demonstrably identical across scenarios are treated as canceling out and are not explicitly modeled. For this analysis, no differential simplification was applied. All processes within the defined system boundaries, including those common across scenarios, were included to provide transparent and comprehensive accounting of environmental impacts. This assessment does not evaluate compliance with New Jersey's Recycled Content Law (N.J.S.A. 13:1E-99.135 et seq.). The system boundary is designed to evaluate environmental impacts associated with polymer recovery via advanced recycling, rather than the production of post-consumer recycled content as defined under New Jersey statute.

2.2 Methodology

The software SimaPro Craft was used for the LCA modeling. The inventory of operational inputs and outputs for the model were developed from scientific literature. A table of the scientific literature utilized can be found in Section 3-1 Literature Sources. Methodology assumptions were refined in consultation with NJDEP and are documented in this report. The results were analyzed to identify

emission hot spots and anomalies. Sensitivity analyses were performed based on the results interpretation to identify how changes in certain assumptions or input data affect the overall results.

2.2.1 Modeling Tool

The SimaPro Craft (Version 10.2.0.0, released March 2025) LCA software was used to model the scenarios. The scenarios were built in the model by using selections of characterization factors that quantify the impacts of a material (e.g., a catalyst) or activity (e.g., transportation in a truck). The characterization factors were extracted from two databases: Ecoinvent (Version 3.11, compiled in March 2025), and the U.S. Life Cycle Inventory Database (USLCI+, Version 1.2024-10.0), both of which were the newest versions available as of May 13, 2025. Ecoinvent is a large database with characterization factors that span diverse materials and activities. However, many are specific to Europe. USLCI+ is centered on the United States and has more precise characterization factors for power generation supply chains.

After the characterization factors were selected, a life cycle impact assessment (LCIA) method was executed in SimaPro Craft. A life cycle impact assessment method maps the data of the characterization factors (e.g., quantity of electricity consumed) to environmental impacts that have implications which are easier to interpret (e.g., impact on global warming).

The LCIA method used for this study was ReCiPe (h) (Version 1.1, released in 2016). ReCiPe displays the impacts organized by single environmental problems (called midpoints) and higher aggregation levels (called endpoints). Midpoint results are useful because they make it easier to differentiate between specific stressors, but midpoint results do not allow for comparison across stressors. In contrast, endpoint, damage related, results have more uncertainty (e.g., the sensitivity of the endpoint area to the midpoint stressor may fluctuate over time, the synergies/antagonisms between midpoint stressors involve many assumptions) but provide a broader perspective on impacts.

The ReCiPe (h) method, or ReCiPe (Hierarchist), is one of three cultural perspectives including the Individual (I) and Egalitarian (E) approaches (PRé Sustainability 2025), seen in **Figure 2.1**. The Hierarchist perspective is based on scientific consensus and are better applied to policy. Whereas the other perspectives consider different timescales, risk, and confidence of impacts.

	Time perspective	Manageability	Required level of evidence
Individualist (I)	Short time	Technology can avoid many problems	Only proven effects
Hierarchist (H)	Balance between short and long term	Proper policy can avoid many problems	Inclusion based on consensus
Egalitarian (E)	Very long term	Problems can lead to catastrophe	All possible effects

Source: PRé Sustainability 2025

Figure 2.1 Three Cultural Perspectives Included in ReCiPe

2.2.2 Impact Categories

Figure 2.2 presents the relationship between the 18 midpoint and 3 endpoint ReCiPe categories for the study. **Table 2.1** and **Table 2.2** provide midpoint and endpoint category descriptions, respectively. Although the ReCiPe impact assessment method contains 18 midpoints and 3 endpoints, only 6 midpoints are presented and discussed in this report: global warming, stratospheric ozone depletion, ozone formation human health/terrestrial ecosystems, terrestrial acidification, freshwater eutrophication, marine eutrophication. The selection of priority impact categories can be subjective to decision-maker and project stakeholder preferences including policy and regulation or confidence of the characterization method. These 6 midpoints were selected because as a group they encompass both global-scale issues and regional ecosystem impacts. **Appendix C** contains the raw data associated with full suite of endpoints that should also be considered in the evaluation of these technologies.

Source: PRé Sustainability 2025

Figure 2.2 Linkages Between the Midpoints and Endpoints in ReCiPe

Table 2.1 ReCiPe's 18 Midpoint Impact Categories

Midpoint Impact Category	Indicator	Characterization Factor	Unit of Measure
Global warming	Infrared radiative forcing increase	Global warming potential	kg carbon dioxide (CO ₂) eq to air
Stratospheric ozone depletion	Stratospheric ozone decrease	Ozone depletion potential	kg CFC-11 eq to air
Ionizing radiation	Absorbed dose increase	Ionizing radiation potential	Kilobecquerel Cobalt-60 eq to air
Fine particulate matter formation	Particulate matter 2.5 microns or greater (PM2.5) population intake	Particulate matter formation potential	kg PM2.5 eq to air
Ozone Formation: Terrestrial ecosystems	Tropospheric ozone increase	Photochemical oxidant formation potential: Ecosystems	kg nitrogen oxide (NO _x) eq to air
Ozone Formation: Human health	Tropospheric ozone population intake increase	Photochemical oxidant formation potential: Humans	kg NO _x eq to air
Terrestrial acidification	Proton increase in natural soils	Terrestrial acidification potential	kg sulfur dioxide (SO ₂) eq to air
Freshwater eutrophication	Phosphorus increase in freshwater	Freshwater eutrophication potential	kg P eq to freshwater
Marine Eutrophication	Nitrogen increase in marine water	Marine eutrophication potential	kg N eq to marine water
Human carcinogenic toxicity	Risk increase of cancer disease incidence	Human toxicity potential	kg 1,4-Dichlorobenzene (DCB) eq to urban air
Human non-carcinogenic toxicity	Risk increase of non-cancer disease incidence	Human toxicity potential	kg 1,4-DCB eq to urban air
Terrestrial ecotoxicity	Hazard-weighted increase in natural soils	Terrestrial ecotoxicity potential	kg 1,4-DCB eq to industrial soil
Freshwater ecotoxicity	Hazard-weighted increase in freshwaters	Freshwater ecotoxicity potential	kg 1,4-DCB eq to freshwater
Marine ecotoxicity	Hazard-weighted increase in marine water	Marine ecotoxicity potential	kg 1,4-DCB eq to marine water
Land use	Occupation and time-integrated land transformation	Agricultural land occupation potential	square meter × year annual cropland eq
Water consumption	Increase of water consumed	Water consumption potential	cubic meters water eq consumed
Mineral resource scarcity	Increase of ore extracted	Surplus ore potential	kg Copper eq
Fossil resource scarcity	Upper heating value	Fossil fuel potential	kg oil eq

Source: Huijbregts et al. 2016

Table 2.2 ReCiPe's Three Endpoint Impact Categories

Environmental Problem	Endpoint Impact Category (i.e., Area of Protection)	Damage Pathways
Global warming	Human health	Years of life lost and disabilities created related to increased malaria cases, diarrhea, malnutrition, and natural disasters because of an increased global mean temperature
	Ecosystems (terrestrial)	Species loss related to changing biome distributions because of an increased global temperature
	Ecosystems (freshwater)	Fish species loss because of decreased river discharge
Stratospheric ozone depletion	Human health	Years of life lost and disabilities created related to increased skin cancer and cataracts because of ultraviolet exposure
Ionizing radiation	Human health	Years of life lost and disabilities created related to an increase in cancer and hereditary diseases because of exposure to radiation
Fine particulate matter formation	Human health	Years of life lost related to an increase in cardiopulmonary and lung cancer caused by exposure to primary and secondary aerosols
Ozone formation	Human health	Years of life lost related to an increase in respiratory diseases caused by exposure to ozone
	Ecosystems (terrestrial)	Loss of plant species because of an increase in ozone exposure
Terrestrial acidification	Ecosystems (terrestrial)	Loss of plant species because of a decrease in soil pH
Freshwater eutrophication	Ecosystems (freshwater)	Loss of aquatic species because of increased phosphorus concentrations
	Ecosystems (marine)	
Ecotoxicity	Human health	Years of life lost and disabilities created because of cancer and non-cancer effects of ingesting and inhaling toxic substances
	Ecosystems (marine)	Species loss because of chemical exposure in marine waters
	Ecosystems (terrestrial)	Species loss because of chemical exposure in soils
	Ecosystems (freshwater)	Species loss because of chemical exposure in freshwater
Water consumption	Human health	Malnutrition because of water shortage
	Ecosystems (terrestrial)	Decrease in net primary productivity because of water shortage as a proxy for total species loss
	Ecosystems (aquatic)	Fish species loss because of decreased river discharge
Land use	Ecosystems (terrestrial)	Species loss because of different changing land use (agriculture, forestry, built up). Species loss caused by transforming natural land to used land, including the time it takes to back-transform to natural land.
Mineral resource scarcity	Resource scarcity	Cost increase because of mineral extraction increase
Fossil resource scarcity	Resource scarcity	Cost increase because of fossil extraction increase

2.2.3 Characterization Factors

The environmental impact of the scenarios is based on the amount of pollutants released (e.g., GHGs) or resources consumed (e.g., water) per unit of material, energy or activity.

Ecoinvent and USLCI are two widely used databases for LCAs that provide detailed characterization factors and inventory data. Ecoinvent is a comprehensive global database that was developed in Switzerland. This database includes detailed global information on the inputs, outputs, and environmental impacts associated with various processes and activities across different industries, along with regionalized emissions and resource use. USLCI, developed and maintained by the National Renewable Energy Laboratory, focuses on the North American region. USLCI provides life cycle data on the energy and materials that flow into and out of the environment that are associated with producing a material. Both databases can be accessed through SimaPro Craft, an LCA software that allows users to use these data sets to develop an LCA model to analyze environmental impacts across multiple different scenarios.

The following are definitions of acronyms used in the Ecoinvent database.

Ecoinvent/USLCI Regional IDs:

- {US}: United States – Includes the average national data of all applicable geographies within the United States for a specific process/material
- {RNA}: North America – Includes the average data of all applicable regions within North America for a specific process/material
- {GLO}: Global – Includes the global average data of all applicable world geographies for a specific process/material
- {RoW}: Rest of World – Includes the global average data minus the region-specific data for a specific process/material (e.g., if Ecoinvent offers characterization factors for the United States and Switzerland, the characterization factor for RoW is the global average excluding the United States and Switzerland)
- {NPCC}: Northeast Power Coordinating Council – Characterization factors that originate from specific emissions data generated within the Northeast Power Coordinating Council region

Ecoinvent System Model IDs:

- Cut-off: Allocation, cut-off by classification – System model that allocates environmental burdens to primary producers, while recycled materials and by-products enter the system burden-free, following a recycled content approach
- APOS: Allocation at the Point of Substitution – System model that follows the attributional approach in which the responsibility of waste material is shared between the producers and subsequent users benefiting from the treatment processes (characterization factors with this designation were not used for this study)
- U: Unit Process data set – Contains detailed process-level data, including important inputs and output data, allowing for a closer examination of each process step

- **S: System Process data set** – Represents an aggregated version of a product’s life cycle stage, though it offers less transparency, making it difficult to identify individual process steps

The availability of characterization factors varies for each material and process within the Ecoinvent and USLCI+ databases. When selecting a characterization factor to use, we maintained a consistent selection process as much as possible. For this study, data from Ecoinvent was prioritized as it has a much larger selection of characterization factors. Using characterization factors from the same database (as much as possible) is preferred because different databases are built using different assumptions. Ecoinvent has several regional IDs that provide data around the world. Regional IDs were prioritized based on relevance to New Jersey. Factors with the {US} or {RNA} identification were prioritized because of their applicability to New Jersey. When data corresponding to this region were unavailable, {GLO} and {RoW} factors were selected, as these factors use averaged global data.

Quality Considerations: Assumptions were made during the characterization factor selection process, which have an impact on the LCA results. One major assumption includes the usage of United States–based factors versus a global factor. These global characterization factors often include embedded electricity and fuel impacts, which may not directly correspond to the United States region. While every effort was made to identify commonly used materials (e.g., assuming that defoamers were mineral oil–based instead of silicone-based because of cost-effectiveness), this is likely to differ between different facilities.

Characterization Factor Gaps: Materials and processes presented in literature sources sometimes did not have an exact match for a characterization factor in Ecoinvent or USLCI+. In these cases, the characterization factor chosen was as close of a proxy as possible (e.g., based on constituent elements).

2.2.4 Allocation

When a process step causes the production of multiple products, the impacts can be divided between the coproducts to ensure only the impacts (burdens and benefits) of the components used to make the final product are included in the results. This can be done with either mass allocation or economic allocation, which are defined as follows:

- **Mass allocation:** Impacts are divided between coproducts in proportion to the mass of each. A benefit of this is that it is consistent over time. A risk is that a low-value product could carry disproportionate burden.
- **Economic allocation:** Impacts are divided between coproducts in proportion to the price of each. This is better suited for products with a range of economic relevance, but since it is based on the market value of the products, there is more uncertainty, and the results may fluctuate over time.

For this study, coproducts were managed with mass allocation because of the preference for lower overall uncertainty in the results over time.

2.2.5 Estimating Waste Hauling

Waste hauling is one of two elements of this study (the other being the use of a New Jersey–specific electricity characterization factor) that is tailored to waste management in New Jersey. The figures that follow show the various elements of the waste hauling process, organized as mechanical plastic recycling in **Figure 2.3**, and chemical plastic recycling in **Figure 2.4**.

Figure 2.3 Mechanical Plastic Recycling

Figure 2.4 Chemical Plastic Recycling

The methodology and assumptions for calculating the hauling distances are as follows, with additional details available in **Appendix C**:

- **Fastest Route Selected:** For all of the hauling distances, the fastest route possible (as determined on a navigation application) was selected.
- **Curbside Waste Collection:** M1, and C1 represent the curbside waste collection from homes and businesses. Example emissions include those associated with door-to-door curbside pickup and engine idling. Although these activities have non-zero emission impacts, because of the uncertainty in these data, M1, and C1 were excluded from this analysis. This is done in alignment with Mousania et al. (2024).
- **Hauling from Business/Residential Area to MRF:** M2 and C2 represent the transportation of waste from a business/residential area to the nearest MRF. A list of in-state MRFs that accept plastics was developed, verified, and mapped.

MRFs that were stated to accept Plastic Types 1, 2, and 5 were assumed to be suitable for this study, with the idea that these facilities would accept Plastic Type 6 (PS) in the future if a suitable recycling technology was available. Then, the approximate centroid of each county was designated as the pickup point from which a full truckload of waste would be collected, in alignment with the assumptions of Mousania et al. (2024). The distances from each centroid point to its nearest transfer station and MRF were determined. In every case, the fastest route possible was recorded.

Finally, the centroid-to-MRF distances were weighted by county population. Population weighting accounts for the fact that more waste is likely to be produced in populous areas; therefore, the average distance traveled should be more reflective of distance traveled by waste created in populous areas. These weighted distances were averaged to produce the final value: the transportation distance of waste from a business/residential area to the nearest MRF (M2/C2).

- **Hauling from MRF to Mechanical Recycling Facility:** M3 represents the transportation of waste from MRFs to the nearest mechanical recycling facility in New Jersey. A list of mechanical recycling facilities was developed using publicly available information, with each facility being vetted to confirm they were operational at the time of developing the inventory and undertaking mechanical recycling. For each MRF, the distance to the nearest mechanical recycling facility was determined, recording the fastest route possible. All distances were averaged to determine the final value for M3.
- **Hauling from MRF to Chemical Recycling Facility:** C3 represents the transportation of waste from MRFs to the hypothetical chemical recycling facility in Keasbey, New Jersey.² Following the

² In accordance with the QAPP, for Scenarios 3 through 6, plastic sorted at an MRF is sent to a theoretical centralized chemical recycling facility. As New Jersey lacks such facilities, a facility in Keasbey, New Jersey, serves as the central point for calculating transportation distances from other MRFs. This site was chosen because it is strategically located in an industrial area with similar operators, centrally located between northern New Jersey and Trenton, and accessible via the I-95 corridor. It is not assumed that said facility, as an MRF, will supply a sufficient volume of feedstock to sustain a chemical recycling facility.

same assumptions as M3, the distance from each MRF to the Keasbey facility was determined, then these distances were averaged to determine the final value for C3.

- **Vehicle Type:** The characterization factor used for all hauling is a diesel-powered, short-haul (i.e., less than 300 miles) combination truck.

2.3 Deviations from the Quality Assurance Project Plan

Table 2.3 provides a list of components in this LCA report that deviated from the QAPP (submitted to NJDEP in January 2025). Descriptions of the deviations are also included.

Table 2.3 Deviations from the Quality Assurance Project Plan

Component of the QAPP	Description of Deviation
A6 Information/Data Quality Objectives and Performance/Acceptance Criteria – Precision	The QAPP states that one of the databases used would be the USLCI database. Since USLCI+ was released in 2025, characterization factors from that database are used instead of USLCI factors when available. USLCI+ is the improved version of USLCI, with new characterization factors and improvements in quality and consistency.
B2 Methods for Environmental Information Acquisition – Scenario 1	The QAPP states that Scenario 1 will include the impacts from landfilling. Per NJDEP’s request, landfilling is excluded from this study to keep consistency with the functional unit between all scenarios.
B2 Methods for Environmental Information Acquisition	The QAPP states that the functional unit for the LCA is 1 kg of plastic material. This was updated to specifically be 1 kg of plastic ready for use in the manufacturing process.
B2 Methods for Environmental Information Acquisition – Scenario 2	The QAPP states that the mechanical recycling process takes place at the MRF. This has been corrected to reflect that mechanical recycling takes place at a mechanical recycling facility. The QAPP states that for mechanical recycling, the incoming plastic stream is shredded, washed, and dried. This process was updated to include a necessary sorting step after shredding.
B2 Methods for Environmental Information Acquisition – Pretreatment	The QAPP states that the pretreatment process includes shredding, screening, sorting, washing and floatation, and sensor-based sorting. This was updated to include a drying step after washing, as drying is necessary for pretreatment following the washing of the plastic.
B2 Methods for Environmental Information Acquisition – Scenario 3	The QAPP states that the pyrolysis oil is purified and used as a feedstock in a steam cracker to produce PP, which is then polymerized to produce PP granulate. After polymerization, the PP granulate is extruded to pellets to be consistent with the functional unit for this LCA study.

Component of the QAPP	Description of Deviation
B2 Methods for Environmental Information Acquisition – Scenario 4	The QAPP states that F-T synthesis is a one-step process in which the cleaned syngas is converted at high temperatures into primary products of wax, hydrocarbon condensate, tail gas, and reaction water. The wax then is sent for hydrocracking in the presence of hydrogen, resulting in the chemical split of the wax into hydrocarbon liquids. Hydrogen is extracted from the tail gas or feed syngas stream at a hydrogen recovery unit. The resulting products are fractioned into the final products of diesel, naphtha, and other products. The naphtha then is sent to a cracker to produce PP, which is then polymerized to produce PP granulate. In this LCA study, F-T synthesis was updated to follow the process described in Nuss et al. (2013), which focuses on the production of olefins instead of fuels. F-T synthesis was updated to a one-step process in which the cleaned syngas is converted into primary products of F-T naphtha and distillate. The F-T naphtha is then sent to a steam cracker to produce the propylene monomer, which is polymerized to produce PP granulate. After polymerization, the PP granulate is extruded to pellets to be consistent with the functional unit used for this LCA study.
B2 Methods for Environmental Information Acquisition – Scenario 5	The QAPP states that after pretreatment of the incoming plastic waste stream, the material is dissolved in a melt consisting of mixed oligomers/monomers before it is depolymerized in the presence of methanol vapor and a zinc acetate catalyst. This was updated so that the melt was assumed to be a portion of the incoming plastic that first enters the melt reactor, facilitating the melting of the remaining incoming plastic. The melt is not an additional input. Additionally, a filtration step was added following the melt reactor for contaminate removal. The QAPP states that the recovered monomers are then repolymerized through a multistage process involving esterification, pre-polymerization, and further polymerization. For clarification purposes, esterification is the pre-polymerization step.

3.0 Data Sources

The following sections describe the literature sources used to develop the operational data for this LCA study. The assumptions and identified data gaps are also included in this section. This information is organized in the form of a Life Cycle Inventory, seen in **Appendix A**.

3.1 Literature Sources

Scientific studies served as the primary source of operational data for this study. When the functional unit of a scientific study was different from the functional unit of this study, the quantitative data were scaled (up or down) accordingly.

Most of the studies used as data sources for the recycling scenarios started their recycling processes with the same plastic type that is produced (i.e., to make PP plastic, the process started with waste consisting primarily of PP plastic material), which matches this study. However, the main literature data sources for the pyrolysis of PP (Gracida-Alvarez et al. 2023; Jeswani et al. 2021; Karaba et al. 2025; Xayachak et al. 2023) and the gasification of PP (Javed et al. 2025; Nuss et al. 2013; Xayachak et al. 2023) started their processes with feedstock different than this study (i.e., plastic that consisted of a mixture of plastic waste material or biodegradable organic waste). The methodology for how the operational data were handled in this study is noted in the “Assumptions” and “Data Gaps” sections.

Table 3.1 presents the sources of operational data used in this study, assessed for quality using the U.S. Environmental Protection Agency’s (EPA’s) data quality pedigree matrix (EPA 2016). A score of 1 represents the highest quality and 5 represents the lowest.

The data quality pedigree matrix’s flow indicators were used to assign the scores. A summary of each quality category is as follows:

- **Flow reliability:** Scored based on whether the data source relies on direct measurements or estimates.
- **Temporal correlation:** Scored based on the age of the data.
- **Geographical correlation:** Scored based on the number of levels of resolution between the source data and the study.
- **Technological correlation:** Scored based on the number of equivalent technology categories.
- **Data collection methods:** Scored based on how representative the data is to the relevant market.

Table 3.1 Data Quality Pedigree Matrix for Operational Data Sources

	Flow Reliability	Temporal Correlation	Geographical Correlation	Technological Correlation	Data Collection Methods
Waste Collection and Sorting					
Estimated transportation distances, using the methodology from Mousania et al. (2024)	3 Calculated distances	4 Oldest data from 2014	1 Existing New Jersey facilities used in assumptions	1 Only facilities matching parameters of this study used (e.g., only MRFs that accept plastic waste)	2 Facility types and locations are from NJ.gov and ENF Recycling n.d. (an industry website).
Pressley et al. (2015)	2 Operational data estimated from a different study, supported by discussions with MRF operators and equipment vendors	4 Data are from a 2012 thesis (Combs 2012). This study was published in 2015.	2 Geography is unspecified, although data are based on recycling composition for the Seattle, Washington, region.	1 Data provided for single-stream MRFs	5 The Combs [2012] thesis used data from 4 MRFs
Estimated material losses from sorting, from The Recycling Partnership (2020)	4 This values is based on The Recycling Partnership's 2016 State of Curbside Report, which uses a national average	3 Data are from The Recycling Partnership's 2016 study	2 Data is a US average	1 This national average value is assumed to be a good representation of NJ's process design, operating conditions, material quality, and scale.	4 The national average is estimated to represent 28% of US homes that could potentially receive curbside recycling service
Virgin Plastic Production					
Estimated transportation distances, using methodology from Mousania et al. (2024)	3 Calculated distances	3 Oldest data from 2016	1 Existing New Jersey facilities used in assumptions	1 Only facilities matching parameters of this study used (e.g., only transfer stations)	1 Facility types and locations from NJ.gov
Franklin Associates (2022, 2021, 2020)	1 Operational data obtained from processing facilities	2 Studies published in 2020, 2021, and 2022	3 Focus on North America	2 Data provided for producing virgin plastic resin before extrusion	5 Data from seven PET producers, three PP producers, and five PS producers

	Flow Reliability	Temporal Correlation	Geographical Correlation	Technological Correlation	Data Collection Methods
Mechanical Recycling of PET and PP					
Uekert et al. (2023)	2 Operational data adapted from other studies	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	2 Uekert et al. (2023) focused on mechanical recycling of PET and PP like this study but does not include waste collection and sorting.	5 Data from two LCA reports
Pretreatment of PET					
Uekert et al. (2023)	2 Operational data estimated from other studies	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	2 Uekert et al. (2023) followed the same pretreatment process as this study but did not include sorting at an MRF.	5 Data from one LCA report
Franklin Associates (2018)	1 Operational data obtained from reclaimer and processing facilities	3 Report was published in 2018	3 Focus was on North America	1 Data provided for bale-to-flake pretreatment process of PET	5 Data from seven PET reclaimer facilities
Pretreatment of PP					
Uekert et al. (2023)	2 Estimated operational data from other studies plus web resources	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	2 Data on material retention from bale to flake are from a dissolution process only, but they are specific to PP.	5 Data from an unknown number of facilities
Franklin Associates (2018)	1 Operational data obtained from reclaimer and processing facilities	3 Report was published in 2018	3 Focus was on North America	2 Data corresponds to pretreatment of high-density polyethylene (HDPE). While it is not PP, it is still a polyolefin.	4 Data from 16 different facilities

	Flow Reliability	Temporal Correlation	Geographical Correlation	Technological Correlation	Data Collection Methods
Pretreatment of PS					
Major data gaps are described in the “Data Gaps” section.					
Pyrolysis of PP					
Gracida-Alvarez et al. (2023)	1 Operational data from pyrolysis facilities	1 Study published in 2023	2 Focus was on conditions in the United States (seven of eight facilities were in the United States)	2 Gracida-Alvarez et al. (2023) focused on HDPE and low-density polyethylene (LDPE). This study focused on pyrolysis of PP.	5 Eight pyrolysis facilities provided data
Jeswani et al. (2021)	2 Estimated operational data from other studies plus a technology developer	2 Study published in 2021	5 German data sets used for fuels, electricity, heat	2 Jeswani et al. (2021) included a mix of polyethylene (PE), PP, and PS. This study focused on pyrolysis of PP.	5 Data on pyrolysis process came from single technology developer
Karaba et al. (2025)	2 Operational data from experiments in the study and other studies	1 Study published in 2025	5 Samples provided from a Czech Republic refining and petrochemical company	3 Karaba et al. (2025) included mixed waste plastic feedstock at the laboratory scale. This study focused on pyrolysis of PP waste at the commercial scale.	5 Data from samples generated from petrochemical facility in the Czech Republic
Xayachak et al. (2023)	2 Estimated operational data from other studies	1 Study published in 2023	5 Australian data sets used for electricity	2 Xayachak et al. (2023) focused on gasification for producing high-value chemicals. This study focused on PP specifically.	4 Data came from 15 peer-reviewed articles.

	Flow Reliability	Temporal Correlation	Geographical Correlation	Technological Correlation	Data Collection Methods
Gasification of PP					
Xayachak et al. (2023)	2 Estimated operational data from other studies	1 Study published in 2023	5 Australian data sets used for electricity	2 Xayachak et al. (2023) focused on gasification for producing high-value chemicals. This study focused on PP specifically.	4 Data came from 15 peer-reviewed articles.
Nuss et al. (2013)	2 Estimated operational data from other studies and technical reports	4 Study published in 2013	2 Nuss et al. (2013) used United States–specific background data.	3 Nuss et al. (2013) focused on gasification/F-T synthesis/steam cracking into ethylene from biodegradable waste.	5 Data came from peer-reviewed articles.
Javed et al. (2025)	2 Estimated operational data from another study that used an industry report	1 Study published in 2025	5 Data from Japan Containers and Packaging Recycling Association	3 Javed et al. (2025) focused on the production of syngas by gasification of unspecified mixed plastic waste.	5 Data came from peer-reviewed articles.
Saebae et al. (2020)	2 Operational data originated from experiments in the study and other studies.	2 Study was published in 2020	5 Background data from the United Kingdom and China	3 Saebae et al. (2020) focused on simulated gasification of PE and PP waste for syngas production.	5 Data came from peer-reviewed articles and simulation experiments.
Methanolysis of PET					
Uekert et al. (2023)	2 Estimated operational data from an industry report	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	2 Uekert et al. (2023) study of methanolysis focused on PET but did not include waste collection and sorting.	4 Data based on commercial-scale methanolysis process as described by an industry report.

	Flow Reliability	Temporal Correlation	Geographical Correlation	Technological Correlation	Data Collection Methods
Dissolution of PP					
Uekert et al. (2023)	2 Estimated operational data from other studies	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	2 Uekert et al. (2023) study of dissolution focused on PP but did not include waste collection and sorting.	5 Data came from a peer-reviewed article.
Dissolution of PS					
Achilias et al. (2009)	5 Operational data based on laboratory-scale study	5 Study was published in 2009	5 Achilias et al. (2009) used European Union background data.	3 Achilias et al. (2009) dissolution is focused on PS, but it is done on a laboratory scale.	5 Data came from a peer-reviewed article and laboratory study.
Uekert et al. (2023)	2 Estimated operational data from other studies	1 Study was published in 2023	2 Uekert et al. (2023) used United States–specific background data.	4 Uekert et al. (2023) dissolution is focused on PP, PET, HDPE, and LDPE, but it uses relevant operational conditions.	5 Data came from a peer-reviewed article and laboratory study.

3.2 Assumptions

The following list of assumptions, organized by process, were used for the modeling:

Waste Collection and Sorting

- A 17 percent (%) material loss was assumed to occur at the MRF for all recycling processes and plastic types. The impacts from hauling and disposing of this 17% material loss were not accounted for in this study, as the study was only focused on impacts related to the plastic evaluated in each scenario and not the other type of materials included as part of the material loss. However, impacts of energy use from sorting out the 17% material loss are included. It was assumed that this 17% material loss is composed of a mixture of municipal solid waste (e.g., paper, other plastic types, organic material) (The Recycling Partnership 2020).
- Electricity consumption at an MRF sorting single-stream materials is 6.2 kilowatt-hours per metric ton, according to Pressley et al. (2015).

Virgin Plastic Production

- Virgin plastic production was assumed to be the production of the plastic, followed by extrusion.

- Material losses from virgin plastic production were assumed to be the 2% loss of materials from extrusion. Any other impacts from virgin plastic production were assumed to be encompassed in the single characterization factor used.

Mechanical Recycling

- Operational data for the mechanical recycling of PP and PET were based on Uekert et al. (2023).
- Material losses were assumed to be divided evenly between the shredding/sorting and washing process steps, excluding the 2% loss of materials because of extrusion.
- The amount of energy consumed in each step of the mechanical recycling process was based on the energy consumption stated in Uekert et al. (2023), where 90% of energy consumed is used for drying, melt extrusion and filtration, pelletization, and polymerization. Thus, 90% of the energy (electricity and natural gas) was divided equally across each relevant process step (drying, extrusion, pelletization, and polymerization) for mechanical recycling. The other 10% of energy consumed was divided equally across the remaining process steps (shredding/sorting and washing).
- For PET, the aluminum compounds included in the washing step are assumed to be aluminum sulfate, as this is a common compound used to remove the contaminants from water that are separated from the plastic during this step (Water & Wastewater 2024).

Pretreatment

- The pretreatment process was assumed to include the following steps based on Zou et al. (2023): Shredding, sorting, washing, separation, drying, and additional sorting.
- Pretreatment losses in the bale-to-flake steps were assumed to be the same across the recycling scenarios for the same plastic types.
- Material losses from pretreatment were assumed to include any mixed solid waste (i.e., residuals from the pretreatment processes that are considered non-recyclable solid waste) from pretreatment process steps.
- The impacts from the hauling and disposal of material losses from pretreatment were not accounted for in this study.
- Pretreatment of PP was assumed to require the same quantities of materials and energy as the pretreatment of HDPE because they are both polyolefins.
- The washing agents for pretreatment were assumed to be a detergent (soap) and a surfactant (sodium hypochlorite or sodium sulfate), based on the information described in Kol et al. (2021) and Ciuffi et al. (2024).
- The amount of energy consumed in each step of the bale-to-flake pretreatment of PP waste was based on the energy consumption described in Franklin Associates (2018). The energy was divided equally across each relevant process step for pretreatment (e.g., if there were five steps for pretreatment that used electricity, the electricity consumed in each step was the total electricity consumption value divided by 5).

- Pretreatment of PP was assumed to have 8% loss of materials, as described in Uekert et al. (2023). This material loss was assumed to be split evenly across the pretreatment steps.
- The amount of energy consumed in each step of the bale-to-flake pretreatment of PET waste was based on the energy consumption described in Uekert et al. (2023). The energy was divided equally across each relevant process step for pretreatment (e.g., if there were three steps for pretreatment that used natural gas, the energy consumed in each step was the total natural gas consumption value divided by 3).
- Pretreatment of PET was assumed to have a 7% loss of materials, as described in Uekert et al. (2023). This material loss was assumed to be split evenly across the pretreatment steps.
- Operational data for the pretreatment of PS were based on the operational data for HDPE bale to flake described in Franklin Associates (2018), owing to PS being more similar to HDPE than to PET in terms of polymer backbone structure, solubility and recyclability approaches, and lack of ester linkages. Also, the operational data were not available for the pretreatment of PS.
- The amount of energy consumed in each step of the bale-to-flake pretreatment of PS waste was based on the energy consumption described in Franklin Associates (2018) for HDPE pretreatment. The energy was divided equally across each relevant process step for pretreatment (e.g., if there were five steps for pretreatment that used electricity, the electricity consumed in each step was the total electricity consumption value divided by 5).
- Pretreatment of PS was assumed to have an 8.6% loss of materials, based on the average material retention of all polymers (PP, PET, HDPE, LDPE) for bale to flake, as reported in the Uekert et al. (2023) supplementary information. This material loss was assumed to be split evenly across the pretreatment steps.
- For the washing step in the pretreatment of PET, PP, and PS, the aluminum compounds included are assumed to be aluminum sulfate, as this is a common compound used to remove the contaminants from water that are separated from the plastic during this step (Water & Wastewater 2024).

Pyrolysis

- The data used for this study correspond with the Gracida-Alvarez et al. (2023) “pioneer plant,” with a capacity of less than 50,000 metric tons per year. This was chosen as the more conservative option compared to Nth plants (i.e., a mature production facility that uses commercialized technology with demonstrated performance at scale) with capacities over 50,000 metric tons per year, which were assumed to be more efficient.
- The inert gas used as an input for the pyrolysis conversion step was assumed to be nitrogen, based on Xayachak et al. (2023).
- Gracida-Alvarez et al. (2023) describes the option of purifying pyrolysis oil. The choice to include the purification step for this study was justified based on the assumption of the plastic-derived pyrolysis oil having contaminants and impurities present that would compromise process efficiency and product quality (Kusenberget al. 2022). A sensitivity analysis was performed without the inclusion of the purification step to compare results.

- The propylene yield from steam cracking is assumed to be 9.3% of the feedstock material, based on the averages of Samples A through G in Table 4 of Karaba et al. (2025). The coproducts from steam cracking are assumed to be the averages of Samples A through G in Table 4 of Karaba et al. (2025).
- In the steam cracking step, the pyrolysis oil was assumed to replace 5% of the feedstock, starting with the naphtha portion of the feedstock. The feedstock for steam cracking was assumed to be 5% pyrolysis oil, 1% conventional naphtha, and 94% virgin fossil-fuel derived ethane, propane, and butane gas, as stated in Gracida-Alvarez et al. (2023).
- In the steam cracking step, the amount of water needed (water to be converted into steam) is adopted from Nuss et al. (2013) for the steam cracking of F-T-derived naphtha, as the amount of water needed for the steam cracking of pyrolysis oil could not be found.
- The polymerization and extrusion to pellets steps were adopted from Franklin Associates (2018) (i.e., PP plastic cradle to gate) to produce PP pellets.
- Items identified as byproducts created from the process steps are: fuel gas, char, ethylene, heavy oil, butadiene, and other olefins. The impacts from creating these byproducts was separated from the impacts of this study by way of mass allocation. These byproducts were not used as process inputs.

Gasification

- The amount of water, energy, and material loss for the gasification and cleaning of gases were based on Javed et al. (2025). The water, fuel, and material loss were divided equally across these two steps.
- Operational data for the gasification step were based on data from Javed et al. (2025), following the steam-gasification process.
- Operational data for the cleaning of gases were assumed to be based on Javed et al. (2025) and Xayachak et al. (2023).
- The amount of syngas generated from gasification that enters into the cleaning of gases step was assumed to have the composition described in Saebae et al. (2020), based on Javed et al. (2025). To convert units from normal cubic meters to kg of syngas, the syngas was assumed to have ideal gas properties (1 kilomole = 22.414 normal cubic meters, based on the ideal gas law at 0 degrees Celsius [°C] and 1 atmosphere).
- Chemical inputs for the cleaning of gases step (sodium hydroxide, feldspar, activated carbon, and zeolite powder) were adopted from Javed et al. (2025) and Xayachak et al. (2023), given these are common compounds used for syngas purification.
- The F-T synthesis and cracker steps were based on Nuss et al. (2013). The oxygen input, CO₂ outputs (not emission, extracted from feedstock), and electricity generated from F-T synthesis were not included in this study because Nuss et al. (2013) was based on a biodegradable, organic feedstock.
- A 14.6% propylene yield from the cracker feedstock assumed was based on Nuss et al. (2013) for F-T naphtha cracking.

- The composition of syngas was based on Table 3 in Saebae et al. (2020). The feedstock was PE and PP.
- The polymerization and extrusion to pellets steps were adopted from Franklin Associates (2018) (PP plastic cradle to gate) for the production of PP pellets.
- The catalyst included in the F-T synthesis step was assumed to be an iron-based catalyst, based on National Energy Technology Laboratory (2025), a U.S. Department of Energy source on F-T synthesis.
- Items identified as byproducts created from the process steps are: char, slag, F-T distillate, ethylene, butadiene, olefins, paraffins, c5+liquids, and alkylenes. The impacts from creating these byproducts was separated from the impacts of this study by way of mass allocation. These byproducts were not used as process inputs.

Methanolysis

- The amount of waste (i.e., plastic disposed of in a landfill) generated from the methanolysis process was based on material loss (approximately 17%), as described in Uekert et al. (2023). The loss of materials was ratioed based on the product recovery of the monomers and the four process steps that experience loss of materials (i.e., there were four steps that had material loss, where 2% of the material is lost during extrusion, 1% loss of material is lost during polymerization, material loss from monomer recovery is based on the monomer product recovery- 88% recovery of DMT and 80% recovery of ethylene glycol, and the remaining percent of material loss is allocated to the filtration process).
- The percent of product recovery (i.e., monomers and repolymerized PET) was assumed to be the same as the percent of product recovery stated in Uekert et al. (2023).
- The amount of energy consumed in each step of the methanolysis process was based on the energy consumption described in Uekert et al. (2023). The energy was divided equally across each relevant process step for methanolysis (e.g., if there were nine steps after pretreatment that used natural gas, the energy consumed in each step was the total natural gas consumption value divided by 9).
- The melt described in Uekert et al. (2023) was assumed to be a portion of the incoming plastic stream that first enters the melt reactor to facilitate the melting of the remaining incoming plastic stream in the melt reactor.
- The DMT monomer was assumed to be 75.6% of the PET polymer, and the ethylene glycol monomer was assumed to be 24.4% of the PET polymer. These mass percent values are derived from the molecular weights of the monomers used in the DMT route for PET synthesis (EPA, n.d.).
- The characterization factor for zinc acetate used in the methanolysis step is assumed to be zinc, as there is no characterization factor for zinc acetate. Zinc was chosen as a proxy in the model to capture a component of the real material's impacts.
- The characterization for antimony trioxide used in the polymerization step is assumed to be antimony, as there is no characterization factor for antimony trioxide. Antimony was chosen as a proxy in the model to capture a component of the real material's impacts.

- Items identified as byproducts created from the process steps are: dimethyl terephthalate and recovered ethylene glycol. The impacts from creating these byproducts are included in the impacts of this study because they were used as inputs into later process steps.

Dissolution

- Following collection and sorting, the operational data for the dissolution of PP were assumed to be the same as the operational data outlined in Uekert et al. (2023).
- The amount of energy consumed in each step of the dissolution of PP process was based on the energy consumption described in Uekert et al. (2023). The energy was divided equally across each relevant process step for dissolution (e.g., if there were six steps after pretreatment that used electricity, the fuel consumed in each step was the total electricity consumption value divided by 6).
- Natural gas consumption for the dissolution process was excluded because the total fuel consumption for dissolution consists of electricity only and not natural gas, as described in Uekert et al. (2023).
- The material loss for the dissolution of PP (2.5%) was based on the average material loss subtracted by the standard deviation described in Uekert (2023) to account for the 2% loss of material from extrusion. Uekert et al. (2023) describes the material recovery for the dissolution process as $98.6\% \pm 1.1\%$. To capture the 2% loss of materials from extrusion, 97.5% was assumed to be the product recovery from dissolution.
- Because electricity usage for the dissolution of PS was not found in literature, the life cycle inventory (LCI) used the average of the electricity required for the dissolution of PP, HDPE, LDPE, and PET, as described in the Uekert et al. (2023) supplementary information. The LCI showed that the amount of electricity required has a standard deviation of 0.0026 kilowatt-hours of electricity, illustrating there is little variation in the electricity required for the dissolution process.
- For the dissolution of PS, the numerical value for the amount of inert gas used in the dissolution process was assumed to be the same numerical value as described in Uekert et al. (2023). Uekert et al. (2023) modeled the dissolution of four different plastic polymers (PP, PET, HDPE, and LDPE), and the operational data for each polymer modeled had the same numerical input for the quantity of inert gas consumed.
- For the dissolution of PS, xylene and methanol were assumed to be the solvent and antisolvent, respectively, as described in Achilias et al. (2009). While Achilias et al. (2009) is a laboratory-scale study, it used similar operational conditions as those described in Uekert et al. (2023), resulting in high product recovery (e.g., plastic dissolved in solvent at an elevated temperature [100°C] for 30 minutes, dried at 80°C, has a three-to-one antisolvent-to-solvent ratio by volume, and has a 97.9% material recovery).
- For the dissolution of PS, the numerical values for the solvent, antisolvent, and material recovery were based on the operational data of the laboratory-scale study described in Achilias et al. (2009).

- For the dissolution of PS, the numerical values for the solvent (xylene) and antisolvent (methanol) emissions to air and recovery were based on the emission operational data for the dissolution of PP (xylene as solvent) and PET (methanol as antisolvent), as described in Uekert et al. (2023).

General

- The study only accounts for impacts related to the specific type of plastic considered in each scenario. For example, in a PET-focused scenario, only the impacts associated with PET waste are included in the analysis. Energy related to removing contamination from the material is included, but the hauling and disposal of other plastics and waste types is excluded.
- The plastic material leaves the MRF in the form of bales. The material is then washed and flaked (i.e., shredded) at the mechanical/chemical recycling facility. The criteria for bale grades (i.e., A, B, C) varies by plastic type. Because of project limitations, a bale grade was not specified for this study. However, the assumption that approximately 7% to 9% of the bale (depending on the plastic type) is removed during the pretreatment process has some alignment with the quality most commonly seen with Grade B bales (Association of Plastic Recyclers 2022).
- Some literature sources indicate that certain coproducts can be used as fuel sources when the process is executed again in the future. For this study, the energy/material inputs are the quantities required to run the process without inputs from previous executions of the process. This study also assumes that by-products are not sold for emission credits.
- Nitrogen was assumed to be the inert gas, as literature (Advanced Gas Technologies n.d.) states that nitrogen is commonly used as an inert gas for physical and chemical recycling of plastic waste.
- Extrusion (included in all scenarios) was assumed to account for 2% of plastic material losses, based on a web resource (Polymer Process 2025).

3.3 Data Gaps

The following list of data gaps are the remaining items that could not be identified for the development of this study's model:

Waste Collection and Sorting

- No data gaps were identified.

Virgin Plastic Production and Landfilling

- It is unclear if the characterization factors used for production of plastic from virgin materials includes an extrusion step to shape the plastic into a pellet form.

Mechanical Recycling

- No data gaps were identified.

Pretreatment

- Operational data for the pretreatment of PS

- Operational data for the electricity and natural gas required for each step in the pretreatment of PP and PET

Pyrolysis

- Operational data for pyrolysis recycling technology representative of a plastic-to-plastic scenario. The 5% pyrolysis oil substitution rate used in this study, adapted from Gracida-Alvarez (2023), may not be a realistic representation of pyrolysis in practice because of the larger portion of plastic-derived pyrolysis oil compared to virgin naphtha. However, the operational data were readily available. The one-to-three (1:3) weight-percent (wt%) ratio (1.5% substitution rate), based on Kusenberg et al. (2022), is more aligned with literature studies and commercial practices; however, it is less representative of a plastic-to-plastic comparison. The operational data for the sensitivity analysis were also adapted from Gracida-Alvarez et al. (2023), owing to the data being readily available.
- A plastic-to-plastic comparison without dilution (i.e., using virgin naphtha) of pyrolysis oil would require significant upgrading (purification) of the pyrolysis oil to ensure 100% pyrolysis oil input would be within the tolerance limits of the steam cracker. A full plastic-to-plastic process of 100% pyrolysis oil is not currently in practice anywhere.
- Operational data for the pyrolysis and steam cracking of plastic waste feedstock consisting of pretreated PP (not mixed plastic feedstock or untreated plastic feedstock). This is particularly meaningful because the main literature data sources for the pyrolysis of PP (Gracida-Alvarez et al. 2023; Jeswani et al. 2021; Karaba et al. 2025; Xayachak et al. 2023) started their processes with plastic consisting of a mixture of plastic waste material, which differs from how this study starts the recycling process with the same plastic that is produced (i.e., to make PP plastic, the process started with waste consisting primarily of PP plastic material).
- Operational data for the electricity, natural gas, and water required for the steam cracking process.
- Operational data for the amount of liquified petroleum gas needed in the purification process step.

Gasification

- Operational data for the combination process of gasification, cleaning of gases, F-T synthesis, and steam cracking for plastic monomer recovery from a pretreated PP waste feedstock. This is particularly meaningful because the main literature data sources for the gasification of PP (Javed et al. 2025; Nuss et al. 2013; Xayachak et al. 2023) started their processes with plastic consisting of a mixture of plastic waste material, which differs from how this study starts the recycling process with the same plastic that is produced (i.e., to make PP plastic, the process started with waste consisting primarily of PP plastic material).
- Operational data for the cleaning of gases
- Operational data for F-T synthesis from syngas generated from the gasification of PP waste

Methanolysis

- The following operational data inputs do not have a representative emission factor in Ecoinvent or USLCI+:
 - Zinc acetate ($\text{Zn}(\text{OAc})_2$)
 - Antimony trioxide

Dissolution

- Operational data for the dissolution of PS (e.g., due to data availability this study used data from a lab scale study from 2009 (Achilias et al.), which may have limited applicability for this study).

General

- Up-to-date information regarding the location of operating MRFs and mechanical recycling facilities statewide would provide more accurate waste hauling distances. For this study, the data source for MRF locations is from 2016 (NJDEP Division of Sustainable Waste Management 2016), and the data source for mechanical recycler locations is from a nongovernment website that was vetted for this study (ENF Recycling n.d.).
- When literature specified a product by its function (e.g., defoamer), every effort was made to identify a characterization factor for a commonly used material (e.g., it was assumed that defoamers were mineral oil based instead of silicone-based due to cost). However, the exact material used is unknown. A future study could consider getting the details on the specific materials used from a recycler NJ.
- Ecoinvent characterization factors use the electricity factor that corresponds with the factor's specific geography (e.g., a GLO characterization factor uses a global average of electricity). At best, an Ecoinvent characterization factor was available for the US geography, which is still not specific to the NJ region (e.g., the Ecoinvent cooling energy factor corresponds to the global geography, thus its embedded consumption of electricity has characteristics of the global average). Characterization factors specific to the NJ geography are very uncommon at this time, especially for material consumption.
- There is uncertainty about the best electricity characterization factor to use for this study. The characterization factor from USLCI+ is specific to NJ, but is causing an unexpected result of water conservation. The characterization factor from Ecoinvent is a general factor for the US geography, and causes the expected consumption of water.
- Chemical recycling facilities are predominantly private organizations; therefore the full picture of actual operational data is unknown. Data available from scientific literature was considered the best available data. However, usability in other contexts may be limited as there may be unknowns in feedstock limitations, proprietary elements of processes, limited scale operations, or other specific conditions or standards.

4.0 Results

The subsequent sections provide the results of the modeling conducted in SimaPro Craft. When examining these results, please consider the following points:

- **Stacked bar chart:** The graphics are filtered to display and evaluate only the following impact categories (see Section 2.2.2: Global Warming, Stratospheric Ozone Depletion, Ozone Formation-Human Health/Terrestrial Ecosystems, Terrestrial Acidification, Freshwater Eutrophication, and Marine Eutrophication). To display results from multiple impact categories in the same graphic, the stacked bar chart data are illustrated as a percent of the total. **Appendix C** contains the raw data associated with full suite of endpoints that should also be considered in the evaluation of these technologies.
- **Process contribution:** When looking at the material/activity that had the greatest impacts, only those contributing at least 1% or more of the total impact were reviewed. Note that the step ‘Plastic Bale from MRF’ shown in the recycling scenario bar charts encompasses the transportation of the waste from the commercial/residential area to the MRF, the energy needed to sort material at the MRF, and the transportation of the waste from the MRF to the respective recycling facility.

4.1 Impacts Per Scenario

The results in this section are organized by scenario, with the impacts of each plastic type displayed individually.

4.1.1 Scenario 1: Virgin Plastic – Polypropylene, Polystyrene, and Polyethylene Terephthalate

This scenario modeled the impacts of producing plastic from virgin materials. Since the focus of this study is on the recycling processes, these impacts were modeled in SimaPro Craft by selecting a single system process (e.g., “Polypropylene resin, at plant/RNA”). Because this scenario does not have multiple process steps, the bar charts displaying impacts divided by process steps were omitted.

Polypropylene

The following are the activities/materials driving impacts from the creation of PP plastic from virgin materials.

- **Global Warming:** Impacts are primarily driven by upstream extraction and refining of crude oil, along with energy use (electricity and natural gas) during polymer production. Transportation of raw materials and intermediates via ocean freighter and pipeline adds to the burden.

- **Stratospheric Ozone Depletion:** impacts for virgin PP production are primarily linked to upstream emissions from the production and supply of energy carriers (e.g., natural gas, diesel) and refrigerants used in industrial processes. Transportation of raw materials and intermediates via ocean freighter and trucks also contributes to this category.

Polystyrene

The following are the activities/materials driving impacts from the creation of PS plastic from virgin materials.

- **Global Warming:** Impacts are mostly driven by extracted crude oil, consumption of benzene and ethylbenzene styrene, energy sources (mostly electricity and natural gas, with some diesel) used for material processing, and transportation of components via ocean freighter, pipeline, and truck.
- **Stratospheric Ozone Depletion:** Impacts are driven mainly by upstream processes associated with energy production (natural gas, diesel) and transportation activities, including ocean shipping, rail, and trucking.

Polyethylene Terephthalate

The following are the activities/materials driving impacts from the creation of PET plastic from virgin materials.

- **Global Warming:** Impacts are mostly driven by extracted crude oil, consumption of methanol, energy sources (electricity, natural gas, diesel, bituminous coal) used for material processing, and transportation of components via ocean freighter and train.
- **Stratospheric Ozone Depletion:** Impacts mainly from upstream emissions during the production of fuels (bituminous coal, diesel, LPG) and energy carriers, as well as from chemical manufacturing processes. Transportation of components by ocean freighter and rail adds to the overall burden.

4.1.2 Scenario 2: Mechanical Recycling – Polypropylene and Polyethylene Terephthalate

This scenario modeled the impacts of producing PP and PET plastic using mechanical recycling.

Polypropylene

Figure 4.2 shows the impact results of producing PP plastic using mechanical recycling.

Figure 4.1 Impacts of Mechanical Recycling on Polypropylene

- Global warming, ozone formation (human health), and terrestrial acidification:** Across global warming, ozone formation (human health), and terrestrial acidification, the relative contributions of shredding/sorting, washing, post-wash drying, extrusion, and pelletizing are similar. Based on Uekert et al. (2023), about 90% of electricity in mechanical recycling is consumed by drying, melt extrusion and filtration, pelletization, and solid-state polymerization. To reflect this, this LCA allocates 90% of electricity evenly across these four steps (22.5% each), with the remaining 10% split between washing and shredding (5% each). The same approach was applied to natural gas use. This allocation explains the distribution of impacts shown in **Figure 4.1**. For global warming, plastic recyclers can reduce impacts from electricity by incorporating renewable energy sources like solar and wind (most likely in the form of renewable energy credits).
- Stratospheric ozone depletion:** The impacts on stratospheric ozone depletion are driven by the washing step. The washing step includes washing agents like soaps and surfactants. Impacts are not driven by direct emissions of ozone-depleting chemicals, but by upstream nitrous oxide (N₂O) emissions associated with the agricultural production of palm oil used in washing agents. To reduce the impacts on stratospheric ozone depletion, plastic recyclers can consider the efficacy of washing agents that do not use palm oil to avoid upstream N₂O emissions.

- **Freshwater and marine eutrophication:** For freshwater and marine eutrophication, the process step responsible for the highest percentage of impact was washing. Pp washing is a chemically intensive (i.e., detergents and alkaline solutions) process that creates a higher volume of nutrient-loaded emissions to water. The waste from this step is high in biochemical oxygen demand (BOD), chemical oxygen demand (COD), detergents and phosphates that contribute to the eutrophication impacts shown in the bar chart (Franklin Associates: A Division of Eastern Research Group 2018). In addition, upstream production of washing agents and electricity for this step also contributes nutrient emissions to the environment.

Polyethylene Terephthalate

Figure 4.2 shows the impact results of producing PET plastic using mechanical recycling.

Figure 4.2 Impacts of Mechanical Recycling on Polyethylene Terephthalate

- **Global warming, ozone formation (human health), and terrestrial acidification:** Similar to PP - across global warming, ozone formation (human health), and terrestrial acidification, the relative contributions of shredding/sorting, washing, post-wash drying, extrusion, pelletizing reprocessing are similar. This is because the main resource consumed in these steps is electricity, and the study assumption

was that energy consumption was distributed following the same method described for mechanical recycling of PP. For global warming, plastic recyclers can reduce impacts from electricity by incorporating renewable energy sources like solar and wind (most likely in the form of renewable energy credits).

- **Stratospheric ozone depletion:** Similar to PP, the impacts on stratospheric ozone depletion are driven by the washing step. The washing step includes washing agents like soaps and surfactants. Impacts are not driven by direct emissions of ozone-depleting chemicals, but by upstream nitrous oxide (N₂O) emissions associated with the agricultural production of palm oil used in washing agents. To reduce the impacts on stratospheric ozone depletion, plastic recyclers can consider the efficacy of washing agents that do not use palm oil to avoid upstream N₂O emissions.
- **Freshwater and marine eutrophication:** For freshwater and marine eutrophication, the process step responsible for the highest percentage of impact was washing. PET washing is a chemically intensive (i.e., surfactants and alkaline solutions) process that creates a higher volume of nutrient-loaded emissions to water. The waste from this step is high in biochemical oxygen demand (BOD), chemical oxygen demand (COD), surfactants, and phosphates that contribute to the eutrophication impacts shown in the bar chart (Franklin Associates: A Division of Eastern Research Group 2018). In addition, upstream production of washing agents and electricity for this step also contributes nutrient emissions to the environment.

4.1.3 Scenario 3: Pyrolysis – Polypropylene

This scenario modeled the impacts of producing PP plastic using pyrolysis. The results correspond to a 5% substitution rate for the steam cracker, with the purification step included.

Polypropylene

Figure 4.3 shows the impact results of producing PP plastic using pyrolysis.

Figure 4.3 Impacts of Pyrolysis of Polypropylene

- All 6 of the Midpoint Categories Evaluated (Global Warming, Stratospheric Ozone Depletion, Ozone Formation Human Health, Terrestrial Acidification, Freshwater Eutrophication, Marine Eutrophication):** The impacts of the six categories evaluated are dominated by the hydrocracking step. Although the pyrolysis conversion step is more energy intensive (it consumes more electricity and natural gas), this is dominated by the impacts of the hydrocracking step's feedstock, consisting of naphtha, ethane, propane, and butane (in the modeled scenario, the steam cracker feed is approximately 95% virgin hydrocarbons and only 5% pyrolysis oil).

Hydrocracking is an important step for pyrolysis because it converts heavier, low value fractions of the feedstock into lighter and more stable petroleum hydrocarbons. This step's removal of heteroatoms increases the stability of the output hydrocarbons by reducing the reactivity (DOE 2012).

The production of naphtha, ethane, propane, and butane carries substantial upstream environmental loads, including greenhouse gas emissions (driving global warming), N₂O emissions from associated fossil fuel supply chains (contributing to ozone depletion), NO_x and VOC emissions (leading to ozone formation), SO₂ and NO_x emissions (driving terrestrial acidification), and nutrient-related emissions

linked to fuel and chemical production (contributing to freshwater and marine eutrophication). As a result, the embedded upstream impacts of these hydrocarbon feedstocks make hydrocracking the dominant contributor across all impact categories.

4.1.4 Scenario 4: Gasification – Polypropylene

This scenario modeled the impacts of producing PP plastic using gasification.

Polypropylene

Figure 4.4 shows the impact results of producing PP plastic using gasification.

Figure 4.4 Impacts of Gasification of Polypropylene

- Global warming and ozone formation (human health/terrestrial ecosystems):** The gasification step is the dominant contributor to these categories. During gasification, the plastic feedstock (polypropylene) undergoes partial combustion with oxygen and air, producing syngas while releasing CO₂, CO, NO_x, SO_x, and trace hydrocarbons, which drive global warming (CO₂) and ozone formation (NO_x and hydrocarbons). The large demand for electricity and steam also adds upstream burdens that further contribute to global warming.

- **Freshwater and marine eutrophication:** The eutrophication impacts are also dominated by the gasification step, but primarily through upstream supply chains. Electricity and industrial gas production contribute nutrient emissions — phosphorus releases from mining and wastewater discharges (freshwater eutrophication) and nitrogen compounds from power generation (marine eutrophication). The gasification reactor itself is not a direct source of nutrient emissions.
- **Terrestrial acidification:** Terrestrial acidification is instead dominated by the cracker step. This step consumes about eight times more natural gas than any other process. Combustion of natural gas produces NO_x , while upstream natural gas supply chains contribute SO_2 . Both SO_2 (forming sulfuric acid) and NO_x (forming nitric acid) are characterized in ReCiPe as contributors to terrestrial acidification impacts.

4.1.5 Scenario 5: Methanolysis – Polyethylene Terephthalate

This scenario modeled the impacts of producing PET plastic using methanolysis.

Polyethylene Terephthalate

Figure 4.5 shows the impact results of producing PET plastic using methanolysis.

Figure 4.5 Impacts of Methanolysis of Polyethylene Terephthalate

- **Global warming, stratospheric ozone depletion, terrestrial acidification, and eutrophication (freshwater and marine):** These impacts are dominated by the crystallization step. Crystallization likely dominates because of the high cooling demand. Cooling requires electricity and refrigerants (which have global warming impacts (Industrial Refrigeration Pros n.d.)). Electricity for cooling is partly supplied by natural gas and coal, combustion of which produces SO_2 (drivers of terrestrial acidification) and NO_x (contributor to stratospheric ozone depletion) and upstream nutrient emissions (contributors to freshwater and marine eutrophication).
- **Ozone formation (human health and terrestrial ecosystems):** Unlike other impact categories, ozone formation is driven by the polymerization step. The polymerization step includes the consumption of antimony (as a proxy for antimony trioxide) and triphenyl phosphate (as a proxy for triphenyl phosphite). Although these materials have low photochemical reactions in the atmosphere, the ozone impacts caused by this step is likely due to the upstream impacts of producing these materials. Production of antimony involves mining, and smelting, which are energy-intensive processes. Production of triphenyl phosphate involves VOC emissions from the manufacturing process, plus energy use. The energy consumed in the upstream processes is likely fossil fuel powered, which leads to NO_x emissions, which are key precursors to ground-level ozone.

4.1.6 Scenario 6: Dissolution – Polypropylene and Polystyrene

This scenario modeled the impacts of producing PP and PS plastic using dissolution.

Polypropylene

Figure 4.6 shows the impact results of producing PP plastic using dissolution.

Figure 4.6 Impacts of Dissolution of Polypropylene

- **All 6 of the Midpoint Categories Evaluated (Global Warming, Stratospheric Ozone Depletion, Ozone Formation Human Health, Terrestrial Acidification, Freshwater Eutrophication, Marine Eutrophication):** The dissolution reactor and filtration step drives the impacts across all the categories evaluated due to their high demand for steam, electricity, solvents (such as xylene), and refrigerants for cooling. Most impacts are linked to the upstream supply chains for energy and solvents/refrigerants, rather than direct emissions from the dissolution reactor itself.

The second largest impact driver across most of the categories was the precipitation reactor, particularly through its use of hexane as an antisolvent. The precipitation reactor step is nearly 40% of the impacts of ozone formation. Hexane production carries upstream burdens, and small direct emissions of hexane to air act as volatile organic compounds (VOCs) that can enhance NOx cycling and ozone formation in the atmosphere.

- **Marine Eutrophication:** The washing and floatation separation step is a large contributor to marine eutrophication. This step requires chemical inputs (e.g., alkalis, surfactants, coagulants) whose upstream production releases nitrogen- and phosphorus-containing emissions. In addition, wastewater streams from the washing process contribute nutrient-related burdens. Because marine eutrophication is particularly sensitive to nitrogen emissions in LCA methods, these upstream and downstream flows make washing and floatation separation a notable contributor in this category, despite lower overall energy use compared to dissolution and precipitation.

Polystyrene

Figure 4.7 shows the impact results of producing PS plastic using dissolution.

Figure 4.7 Impacts of Dissolution of Polystyrene

- **All 6 of the Midpoint Categories Evaluated (Global Warming, Stratospheric Ozone Depletion, Ozone Formation Human Health, Terrestrial Acidification, Freshwater Eutrophication, Marine Eutrophication):** Impacts are driven by the dissolution reactor and precipitation reactor processes of the six categories evaluated. Both are resource intensive. The dissolution reactor step includes energy (in the form of steam and electricity) and chemical resources (refrigerants for cooling and xylene as a solvent). These inputs drive impacts across categories: energy use contributes to global warming and acidification (CO₂, SO₂, NO_x from upstream power generation), refrigerants contribute to ozone depletion and global warming, and solvent production contributes to eutrophication. The precipitation reactor step uses methanol as an antisolvent and releases a small quantity of methanol as emissions to air, which contributes to ozone formation. Most of the resulting impacts are linked to the upstream supply chains for energy and solvents/refrigerants, rather than direct emissions.
- **Relative importance of precipitation:** The precipitation reactor contributes a larger share of total impacts for PS than for PP. This is likely because the quantity of antisolvent (methanol for PS and hexane for PP) required is nearly 120 times larger for PS than for PP. Operational data were adapted from two different literature sources. For PP, Uekert et al. (2023) reported a 15% weight-to-volume (w/v) plastic-to-solvent ratio with a 1:3 solvent-to-antisolvent ratio; however, these values were later noted as inconsistent with the described process. For PS, the data follows Achilias et al. (2009), which used a 5% w/v plastic-to-solvent ratio and the same 1:3 solvent-to-antisolvent ratio. These conditions result in antisolvent requirements nearly 120 times higher for PS than for PP, which is consistent with the literature.

4.2 Impacts Per Plastic Type

This scenario modeled the impacts of producing a specific plastic type using a range of methods. These figures were created by classifying the scenario with the largest impact as 100% and displaying the results of all the other scenarios as relative in value.

4.2.1 Polypropylene

Figure 4.8 shows the impact results of producing PP plastic.

Figure 4.8 Comparison of Impacts from Five Methods of Producing Polypropylene

- **Gasification:** Gasification is identified as the scenario with the largest impacts across all categories. Gasification has numerous energy-intensive steps (gasification, cleaning of gases, F-T synthesis, cracking), and a variety of chemical compounds are also used. Each of these steps adds complexity and increases the environmental footprint, as more resources are consumed, and more emissions are generated throughout the process.
- **Pyrolysis:** Pyrolysis is the second highest in all impact categories, except for terrestrial acidification, which virgin production is the second highest for. Pyrolysis impacts are influenced by the large share of virgin hydrocarbons in the cracker feedstock assumed in the model, which shifts burdens to upstream fuel and feed production. The inclusion of the purification step adds many chemical inputs (hydrogen, still gas, residual oil, pet-coke, etc.) and increases the amount of energy required for the overall process, all of which contribute greatly to the impact categories.
- **Virgin production:** Virgin plastic production is the third highest in several air-related categories (e.g., climate change and ozone formation), and second highest for acidification, primarily due to upstream extraction and refining of fossil feedstocks and petrochemical preparation for polymerization.
- **Mechanical recycling:** Mechanical recycling shows the lowest impacts in most categories but stands out for marine eutrophication, which is linked to upstream nutrient emissions from washing agents (e.g., palm-oil-based surfactants) and electricity generation used in sorting and reprocessing.
- **Dissolution:** The impacts of dissolution are intermediate relative to the other technologies. Dissolution reflects energy demand and solvent handling in dissolution/precipitation, elevating impacts relative to mechanical recycling but remaining lower than gasification and pyrolysis.
- **Implication:** Process complexity and upstream feedstock burdens are the main differentiators. Technologies with fewer process steps and lower energy demand — or those that reduce reliance on virgin hydrocarbon feedstocks — tend to yield lower overall impacts.

4.2.2 Polystyrene

Figure 4.9 shows the impact results of producing PS plastic.

Figure 4.9 Comparison of Impacts From Two Methods of Producing Polystyrene

- **Virgin production vs. dissolution:** When comparing the creation of polystyrene (PS) plastic using virgin materials and dissolution, neither method consistently performs better across all categories. Virgin production results in higher impacts for global warming, ozone formation, and terrestrial acidification. These burdens are primarily associated with the extraction and refining of fossil feedstocks and the energy requirements for polymerization, which release CO₂, SO₂, and NO_x.
- **Dissolution:** Dissolution shows higher impacts for stratospheric ozone depletion, freshwater eutrophication, and marine eutrophication. These impacts are linked to the use of solvents and antisolvents in the dissolution and precipitation steps (xylene and methanol), as well as their upstream supply chains. Refrigerants for cooling and the electricity required for dissolution also contribute, with methanol use and emissions from the precipitation reactor playing a particularly important role in ozone formation.
- **Implication:** The environmental profile of polystyrene production depends on the specific impact category considered. The choice between virgin production and dissolution should take into account both the relative importance of each environmental concern, as neither method is universally preferable across all categories. Further evaluation may be based around the complete suite of endpoints provided in **Appendix C**.

4.2.3 Polyethylene Terephthalate

Figure 4.10 shows the impact results of producing PET plastic.

Figure 4.10 Comparison of Impacts From Three Methods of Producing Polyethylene Terephthalate

- **Methanolysis:** Methanolysis results in the highest impacts to produce PET plastic across most environmental categories. This is primarily due to the energy and chemical requirements of the methanolysis process, which includes depolymerization, purification, and repolymerization steps. The process is resource-intensive and generates emissions throughout multiple stages.
- **Virgin production:** Virgin PET leads terrestrial acidification, primarily from SO₂ and NO_x associated with upstream extraction/refining and petrochemical production/polymerization. It is also very high in global warming due to the energy intensity of upstream activities.
- **Mechanical recycling:** Mechanical recycling generally shows lower impacts compared to methanolysis and virgin production. Its environmental profile benefits from fewer process steps and reduced energy demand. However, the quality of recycled PET may decline over multiple cycles, which can limit the potential for repeated recycling.
- **Implication:** The choice of production method for PET significantly influences its environmental impact.

4.3 Sensitivity Analysis

A sensitivity analysis uses measured changes to illustrate the impacts of specific variables on the results. Example variables are major assumptions, data gaps, and study decisions. The results can help identify which parameters have the greatest influence on outcomes, and areas in which further research would be the most meaningful.

These figures were created by classifying the scenario with the largest impact as 100% and displaying the results of all the other scenarios as relative in value. In addition to the midpoint results displayed in this section, endpoint data is available in **Appendix C**.

4.3.1 Varying the Characterization Factor of Electricity

This first sensitivity analysis varied the characterization factor selected for electricity consumption. Mechanical recycling of PP was chosen as an illustrative example. This characterization factor was selected because it was noted that the USLCI+ characterization factor (CF) chosen, 'Electricity, AC, 120 V | Electricity, at user, consumption mix - PJM Interconnection, LLC – BA', was unexpectedly showing that the consumption of electricity was responsible for a net return of water to the environment. The best available Ecoinvent characterization factor, 'Electricity, high voltage {US-RFC} | electricity, high voltage, production mix | Cut-off, U', causes the expected consumption of water. In addition, electricity is a common driver of impacts among the scenarios. **Figure 4.11** presents the results.

Figure 4.11 Comparison of Results Using Different Characterization Factors for Electricity

Possible reasons for the net return of water to the environment include land use interactions—for example, electricity generated from land-intensive renewables such as solar photovoltaic may be modeled as reducing demand for irrigated agricultural land, which is water-intensive. Additionally, the water–energy nexus can play a role, such as when electricity from less water-intensive sources displaces electricity from thermal power plants that require significant water for cooling. However, the documentation for USLCI+ does not clearly specify whether such displacement credits are embedded in its characterization factors. By contrast, Ecoinvent consistently reports water consumption because it models direct evaporation and cooling water use at power plants. Therefore, while the results are consistent across most impact categories when, differences in the modeling of water use are a key source of divergence between databases.

PJM Interconnection is a regional grid operator for New Jersey. Since electricity is one of the few elements of this model that can be New Jersey specific, the USLCI+ CF ‘Electricity, AC, 120 V | Electricity, at user, consumption mix - PJM Interconnection, LLC – BA’ was used for all instances of electricity consumption across all the baseline analyses, per plastic analyses, and the other sensitivity analysis.

4.3.2 Varying Components of Pyrolysis (Substitution Rate, Purification)

This sensitivity analyses varied 2 components of the pyrolysis of PP – varying the composition of the feedstock to the steam cracker, and removing the purification step of the pyrolysis oil prior to the steam cracking step.

Varying composition of the feedstock to the steam cracker: This was meaningful to analyze because of the variability in feedstock composition documented in the literature. The ratio of PP-derived pyrolysis oil to conventional naphtha was altered from a 5% substitution rate (5:1) to a 1:3 wt% ratio (equal to a 1.5% substitution rate). A 1:3 ratio is more closely aligned with literature studies and commercial pyrolysis practices, where the feedstock in them steam cracker has a higher proportion of naphtha than pyrolysis oil because of the low-quality nature of the plastic-derived pyrolysis oil (Kusenberget al. 2022). However, the 1:3 ratio is less representative of a plastic-to-plastic comparison and is more reflective of virgin production. There is no purification activity the alternative due to the low substitution rate, dilution of the pyrolysis oil, compared to the baseline scenario (1.5% versus 5%).

Removing purification of the pyrolysis oil: This was included in the sensitivity analysis due to the plastic feedstock being composed of pretreated PP versus a mixed plastic feedstock as described in Gracida-Alvarez et al. (2023), and the feedstock for steam cracking being 95% virgin hydrocarbon. Here, the ratio of PP-derived pyrolysis oil to conventional naphtha was kept at a 5% substitution rate (5:1), but the pyrolysis oil was not purified prior to being used as a feedstock in the steam cracker. The lack of purification of pyrolysis oil prior to steam cracking with a 5% substitution rate is documented in literature because this is considered a low concentration of plastic-derived pyrolysis oil in the steam cracker (Gracida-Alvarez et al. 2023).

Figure 4.12 displays the results comparing the baseline (5% substitution rate with purification, which is seen in Section 4.1.3) with the reduced substitution rate (1.5% substitution rate with no purification) and the removal of the purification step (5% substitution rate without purification).

Figure 4.12 Comparison of Pyrolysis Results Using Different Substitution Rates

- Purification:** The results clearly show that pyrolysis performed with a 5% substitution rate with the inclusion of a purification step has the highest impact across all categories. Purification is performed via hydrotreatment of the pyrolysis oil. This adds hydrogen, natural gas, electricity, combustion of still gas and residual oil, and the handling of petroleum coke that are not included in the other two pyrolysis scenarios.

The hydrogen is sourced via steam methane reformation which generates CO₂ and NO_x which drive global warming potential, terrestrial acidification, and ozone formation. The additional natural gas form NO_x, CO₂ and SO₂ emissions, contributing to global warming, terrestrial acidification, and ozone formation. The NO_x emissions also contribute to the nutrient loading contributing to freshwater and marine eutrophication. As stated in the above scenarios, electricity contributes to all impact categories due to the fossil fuel sources and

emissions. Pet-coke is very sulfur-rich which contributes to acidification and ozone formation. Lastly, the heavy vacuum residue byproduct drives human and ecosystem toxicity as it contains heavy metals, PAHs, and sulfur.

- **Substitution Rate comparison:** Adding a purification step (hydrotreatment) to pyrolysis oil significantly increases impacts across all categories, making the 5% substitution with purification scenario the most impact-intensive overall.

When purification is excluded, lowering the substitution rate from 5% to 1.5% still increases impacts because more virgin naphtha is required in the cracker feed, amplifying upstream fossil extraction and refining burdens. However, this effect is smaller than the purification effect, so the 1.5% scenario remains less impactful than the purified 5% scenario. Pyrolysis oil quality and use of virgin naphtha are highly influential in understanding and determining the impacts of pyrolysis.

4.3.3 Completeness Check

A completeness check is an evaluation that the study includes all necessary information to meet the goal and scope. The following items were evaluated as a part of the completeness check:

- **Inclusion of all relevant process steps:** The recycling processes encompass the major steps for a cradle-to-gate analysis. This includes upstream and downstream flows, even when certain steps are consistent across scenarios, to ensure comparability and transparency.
- **Impact assessment method includes the materials/activities most important to this study:** In any LCA, some elementary flows (i.e., material or energy coming from or going to the environment without further transformation) are not included in the impact assessment method; therefore, they are not represented in the results. SimaPro Craft flags these as “Substances not defined in used method.” In this study, this is occurring to some degree across all scenarios. However, key contributors (specifically greenhouse gases) were confirmed to be included, so the choice of ReCiPe as an impact assessment method was deemed acceptable.
- **Appropriate data coverage:** Transportation distances were assumed using New Jersey-specific data, and a New Jersey-specific characterization factor was chosen for electricity. For other characterization factors, those specific to the United States were chosen when available. When a {US} factor was not available, {GLO} factors (global average data) were chosen first and {RoW} factors (global average data without the region-specific data) were chosen next.

4.3.4 Consistency Check

A consistency check examines whether a study used tools and assumptions in a uniform way. The following items were evaluated as a part of the consistency check:

- **Applied system boundaries consistently:** All scenarios of this study exclude impacts from the use of the plastic before it becomes a waste material. Across all recycling scenarios, the waste is uniformly assumed to be coming to the recycler as burden-free. For all recycling scenarios, material removed from the process streams (because of it being a different type of material from the final plastic) is excluded from the model for all scenarios to keep the impacts focused on those of the final plastic. Since recycling scenarios were the focus of this study, plastic production from virgin materials was modeled as a single process step, whereas the recycling scenarios were modeled as a granular series of process steps.
- **Used the same functional unit:** The same functional unit (1 kg of plastic ready for use in a manufacturing process) was used across all scenarios of this study. For operational data from scientific papers, data were scaled up or down if the functional unit did not align with that of the study.
- **Allocated coproducts in a consistent way:** Mass allocation was applied to all coproducts and byproducts in each scenario. Economic allocation was considered but not used due to high price variability and uncertainty in coproduct markets. This approach ensures consistency and transparency, but we acknowledge that mass allocation may over-assign impacts to high-mass, low-value byproducts that do not drive process demand.
- **Used databases consistently:** When the same material/activity was used across scenarios, the same characterization factor was chosen. The databases used were limited to USLCI+ (because of its geographic alignment) and Ecoinvent (because of its breadth of available characterization factors).

5.0 Discussion and Next Steps

5.1 Considerations of Results

Choice of Functional Unit: The selection of a functional unit is a critical component of any LCA study. If the current functional unit of “1 kg of plastic produced” were to be changed to “1 kg of waste treated,” this would require expanding the system boundaries to include the impacts of redirecting mis-sorted plastics (i.e., managing PET material that ends up in a PP recycling stream). It would also warrant changing the virgin plastic scenario to include landfilling of the material after its use. Analyses that factor in impacts from landfilling may provide valuable insights regarding optimal material management from an environmental perspective. This is a timely consideration as different states take different approaches (e.g., Oregon aims for selective recycling with optimization of landfill operations, while California is working toward aggressive diversion of waste to landfills).

Choice of Allocation: The current analysis shows the results with a mass allocation. Although mass allocation has less variability over time, an argument could be made for economic allocation considering that several of the by-products have notable financial value (e.g., butadiene, fuel gas, paraffins).

Data Sources: As mentioned, all data inputs, except for transportation, were scaled from other studies. While every effort was made to ensure the data were being used in a similar way for this study, each of those other studies have their own uncertainties in data inputs, assumptions, and modeling choices, all of which impact the results. Thus, using said data for this study accentuates those uncertainties. If available, data directly from a recycler would substantially reduce the uncertainty in the results.

High-Level Assumptions: The availability of operational data from literature impacts the reliability of the results. For example, this study assumed that energy consumed during pretreatment is split equally across all pretreatment steps. If this assumption is inaccurate, the current results make the pretreatment steps look more equal than they actually are. If the energy consumed during each pretreatment step was available, it likely would reflect drying being the dominant energy consumer followed by washing and flotation separation (Martín-Lara et al. 2022). In literature, shredding and screening was identified to have moderate energy requirements, and sorting steps had notably lower energy requirements compared to the other pretreatment steps (Martín-Lara et al. 2022). Obtaining data or information directly from a recycler would enhance the accuracy of the results.

Need for Regular Updates: It is important to recognize that LCA studies should be conducted on a regular basis to capture ongoing changes in process inputs, technologies, and characterization factors. For example, as the electric grid transitions to cleaner energy sources, the emissions associated with electricity consumption will decrease, leading to lower environmental impacts in future assessments. Regular updates ensure that LCA results remain relevant and accurately reflect current conditions, supporting better decision-making for sustainability.

5.2 Items Identified for Further Study

Study Applications: This study was a general-purpose life cycle assessment that was not mandated by policy or designed to meet a regulatory or policy standard. Further study refinement and resolution of data gaps should be conducted prior to making decisions based solely on this study. The operational data for this study came from scientific literature. While every effort was made to adapt the literature data to this study (e.g., data were scaled up or down to match the functional unit of this study, and inputs were omitted if deemed a mismatch for this study), the scientific literature comes with its own operating conditions, assumptions, and data gaps, and using those data for this study introduces uncertainty. It is recommended that the study results be used only for information-gathering purposes—to better understand what elements of the plastic-to-plastic recycling process would benefit from more data and clarity.

Next Steps:

- **Literature Review:** Perform an additional literature review on the advantages, disadvantages, limitations, challenges, and variety of approaches associated with each of these recycling technologies, such as the quality and control of the incoming material.
- **Data Collection:** Seek direct operational data from recycling facilities to reduce uncertainty and improve model accuracy.
- **Functional Unit Evaluation:** Consider alternative functional units and expanded system boundaries to capture a broader range of impacts, including mis-sorted plastics and end-of-life scenarios.
- **Process-Specific Data:** Gather detailed information on energy use and material flows for individual process steps to refine impact assessments.
- **Data Gaps:** Focus on data gaps identified from this study to target data gathering for the next phase of the project, that will lead to more refined results.
- **Material Quality and Circularity:** Investigate possible analysis methods to incorporate metrics for material circularity and polymer quality retention to provide a more comprehensive sustainability evaluation.
- **Policy Specific Scenario:** A policy-aligned scenario designed to meet New Jersey's Recycled Content Law would require different feedstock specifications and product quality constraints, likely increasing reliance on virgin polymer and mechanical or dissolution recycling. Such changes would alter impact profiles relative to the advanced recycling pathway evaluated here.

Appendix A Life Cycle Inventory

For the recycling scenarios, the functional unit is 1 kilogram (kg) of plastic ready for use in manufacturing, and the reference flow is 1 kg of output plastic. For the virgin plastic scenario, the reference flow is 1 kg of plastic waste.

In the “NJDEP LCI data collection” spreadsheet, the first six columns for Scenario 1 and eight columns for Scenarios 2 to 6 contain the operational data—these are the inputs and outputs of energy, activity, and materials in each step of the recycling process. **Table A1** describes the information in these columns.

Table A1 Descriptions of Operational Data Columns

Column Name	Description
Process Step Component	This indicates values that are products from previous steps, new inputs, or waste materials.
Numerical Value	This value is the quantity of material, energy, or activity that is input into the system, or waste material/emissions to the environment that is output by the process. It is taken from scientific papers or estimated using literature or information from industry professionals. Modifications are made to balance the mass quantities. For example, if material losses were deemed an important part of a process but the main literature source did not account for material losses, then the numerical data were scaled up to account for material loss.
Unit of Measure	This is the unit of measure stated in the data source (e.g., the journal publication, website).
Numerical Value (converted)	This value is the numerical value scaled up or down to correspond to the reference flow of 1 kg of output plastic (e.g., if the scientific paper reported material inputs needed to produce 1 metric ton of output plastic, the quantities of material inputs are divided by 1,000 in this column to correspond to the production of 1 kg of output plastic).
Unit of Measure (converted)	This is the unit of measure that corresponds to the reference flow.
Type of Material or Activity	This is the name of the material, energy, or activity.
Purpose	If needed, this information provides additional details about the function, material, energy, or activity.
Source/Justification of Product Input	This is the name of the scientific paper or method of estimation. Where applicable, the location within the paper was specified (e.g., Table 1 in supplementary information).

The last three columns contain the characterization factor information. A characterization factor quantifies the impact that a specified amount of energy, material, or activity is responsible for causing.

Table A2 describes the information in these columns.

Table A2 Description of Characterization Factor Columns and Other

Column Name	Description
Input in SimaPro Craft	This is the name of the characterization factor identified as the best fit. The characterization factor is from either the Ecoinvent or USLCI database.
Characterization Factor Notes (related to precision, accuracy, representativeness, completeness, comparability, sensitivity)	This is qualitative commentary on how closely the chosen characterization factor matches the material, energy, or activity.
Other Comments	Any other commentary on the operational data (e.g., mass balance, scaling to reference flow) or characterization factors is included here.

Appendix B Material Quality and Circularity

Although it is excluded from this study, mechanical recycling and chemical recycling have different material quality considerations that impact how many times the same plastic material can go through a recycling process. **Table B1** provides additional information.

Table B1 Material Quality and Circularity Information Across Recycling Types

Recycling method (Scenario)	Polymers modeled	Material quality & circularity (qualitative)	Material quality (dimensionless)*	MCI**	Key references
Mechanical recycling (S2)	PP, PET	Recycled polymer quality is lower than virgin due to thermal/mechanical degradation during melt processing; properties often require blending or down-cycling; circularity low (losses in sorting/pretreatment).	PP: 0.745 ± 0.241 ; PET: 0.748 ± 0.204	PP: 0.27 ± 0.07 ; PET: 0.36 ± 0.09	Jeswani et al. 2021; Uekert et al. 2023
Pyrolysis + steam cracking (S3)	PP	Fully deconstructs polymers to hydrocarbons/monomers; after purification and repolymerization, material can be virgin-like; low circularity due to low monomer yields and material losses; virgin blending commonly needed.	$\approx 1.0^{***}$	—	Gracida-Alvarez et al. 2023; Karaba et al. 2025; Kusenberget al. 2022; Uekert et al. 2023
Gasification (F-T) + steam cracking (S4)	PP	Completely breaks down to syngas/intermediates; after synthesis can yield virgin-equivalent polymer; higher energy demand and low yields → low circularity; virgin blending often required.	$\approx 1.0^{***}$	—	Javed et al. 2025; Nuss et al. 2013; Xayachek et al. 2023; Uekert et al. 2023
Methanolysis (S5)	PET	Depolymerizes to pure monomers (e.g., DMT/EG) and repolymerizes; very high purity and reusability (virgin-equivalent performance); circularity relatively high but affected by process losses.	$\approx 1.0^{****}$	0.89 ± 0.34	Uekert et al. 2023

Recycling method (Scenario)	Polymers modeled	Material quality & circularity (qualitative)	Material quality (dimensionless)*	MCI**	Key references
Dissolution (S6)	PP, PS	Polymer backbone retained; dissolution, filtration, and re-precipitation minimize degradation; high material quality and high circularity when solvent systems are optimized.	PP: 0.900 ± 0.092	PP: 0.91 ± 0.08	Achilias et al. 2009; Uekert et al. 2023

Notes:

* Material quality is reported as the melt flow rate of the recycled plastic divided by the melt flow rate of the corresponding virgin material. Values are reported as the average and standard deviation.

**MCI – Material Circularity Index. It is the circularity of recycled material, as determined by a series of equations, reported as an average and standard deviation.

*** Assumed value given that the monomers generated from pyrolysis and gasification are generally considered to be of equal quality to their virgin counterparts.

**** Per Uekert et al. (2023), the standard deviation is unavailable.

Mechanical recycling results in the lowest material quality because of the degradation in the polymer structure during the melt extrusion process (Jeswani et al. 2021; Uekert et al. 2023). In contrast, dissolution preserves the original polymer structure by avoiding chemical depolymerization and operating at lower temperatures without physical shearing (Achilias et al. 2009; Uekert et al. 2023).

Pyrolysis and gasification fully break down polymers into hydrocarbons or syngas, requiring energy-intensive conditions and complex purification steps. These processes achieve virgin-like polymer quality only after repolymerization, but monomer recovery is low and circularity remains limited due to material losses and the need for virgin blending (Gracida-Alvarez et al. 2023; Shah et al. 2023; Xayachak et al. 2023). Pyrolysis, in particular, is costly and sensitive to feedstock purity, even though it can handle mixed plastic waste (Whajah et al. 2021).

Methanolysis is one of the most circular technologies and retains the highest material quality (Uekert et al. 2023). This is because methanolysis can completely reverse PET back into its original, pure monomers, which are identical to those used to produce virgin PET. From Uekert et al. (2023), based on the melt flow rate guidelines for plastic products, a recycled polymer must have a material quality of at least 0.75 to be processed back into the same product. Mechanical recycling often meets this threshold once before being downgraded into lower-quality products, whereas dissolution of chemical recycling processes should enable at least three recovery cycles (Uekert et al. 2023).

Overall, recycling technologies differ significantly in material quality and circularity. Mechanical recycling offers the lowest quality and limited reuse potential, while dissolution and methanolysis maintain higher-quality polymers and enable multiple recovery cycles. Pyrolysis and gasification can produce virgin-like polymers but require high energy and virgin blending, resulting in lower circularity compared to chemical depolymerization methods like methanolysis.

Appendix C Raw Data

C.1 Transportation Calculations

C.2 Endpoint Results

C.3 Elementary Flow Results

Appendix C.1 Transportation Calculations

	Distance (miles)	Description
M2	8.5	Transportation from county centroid to nearest single-stream materials recovery facility (MRF) that accepts plastics, weighted by county population
M3	25.4	Transportation from MRFs to mechanical recycler
C2	8.5	Transportation from county centroid to nearest single-stream materials recovery facility (MRF) that accepts plastics, weighted by county population
C3	51.9	Transportation from MRFs to Bayshore

	Map	Information Source	Year of Publication
County centroids	https://maps.app.goo.gl/frtThBowHiPzr7G5A	The approximate centroid point was chosen for each of New Jersey's 21 counties	N/A
Transfer stations	https://maps.app.goo.gl/j8c9BD0ZJ8NcBcFi6	https://www.nj.gov/dep/dshw/hwtf/tsicmrfd.htm	2024
MRFs	https://maps.app.goo.gl/p4vnkyhDNcyvRktU8	https://www.nj.gov/dep/dshw/recycling/classa.pdf	2016
Mechanical recyclers	https://maps.app.goo.gl/i2KmHfxLmT65o1XC8	https://www.enfplastic.com/directory/plant/United-States?area1=New%20Jersey	n.d.

Note: each of the lists above were briefly vetted to ensure the facility existed, was operational, operating under the same name and function, etc.

Mechanical/Chemical Recycling Scenario

Transportation from county centroid to nearest single-stream materials recovery facility (MRF) that accepts plastics, weighted by county population

County	MRF Name	Materials Accepted	Address
Atlantic	Atlantic County Utilities Authority Intermediate Processing Facility	Aluminum containers, steel	6700 Delilah Rd, Egg Harbor Township, NJ 08234
Bergen	Interstate Waste Services	Metal, glass, paper, plastic,	60 Railroad Ave, Closter, NJ 07624
Burlington	OTC Services	Aluminum containers, steel	130 Hancock Ln, Westampton Township, NJ 08060
Camden	Republic Services	Aluminum containers, steel	2201 Mt Ephraim Ave, Camden, NJ 08104

Scenario 3 - 5% Sub with Purification

Scenario 3 - 5% Sub with Purification

Calculation/Analyze
Results: Inventory
Product: 1 kg S3.10.sensitivity2 (with purification) Extrusion to Pellets (of project NJDEP LCA 3_3_25 Model)
Method: ReCiPe 2016 Midpoint (H) V1.11 / World (2010) H
Indicator: Inventory
Compartment: All compartments
Per sub-compartment: Yes
Mode: Group
Default unit: No
Exclude input: No
Exclude loss: No
Sorted on: Substance
Sort order: Ascending

Scenario 3

Scenario 3

Calculation/Analyze
Results: Inventory
Product: 1 kg S3.10 Extrusion to Pellets (of project NJDEP LCA 3_3_25 Model)
Method: ReCiPe 2016 Midpoint (H) V1.11 / World (2010) H
Indicator: Inventory
Compartment: All compartments
Per sub-compartment: Yes
Mode: Group
Default unit: No
Exclude input: No
Exclude loss: No
Sorted on: Substance
Sort order: Ascending

No	Substance	Compartment	Sub-compartment	Unit	Total	S3.10 Extrusion to Pellets	S3.9 - Polypropylene	S3.8 - Hydrocarbons	S3.7 - Pyrolysis	S3.6 - Post-consumer plastic	S3.5 - Post-consumer plastic	S3.4 - Plastic	S3.3 - Plastic	S3.2 - Shredded plastic	S3.1 - Plastic Bale from MRF
