1993 Benthic Macroinvertebrate Study

Introduction

Historical Perspective

Since the early 1970's, the Bureau of Water Monitoring has been conducting biomonitoring studies on the state's waterbodies. Biomonitoring conducted by the bureau has included both long-term ambient monitoring and intensive surveys.

Between 1977 and 1988 the **Ambient Station Biomonitoring Network** was sampled in cooperation with USEPA (Region II and Headquarters) and USGS. The resulting biological data was utilized by the 305(b) program in its evaluations of waterbody impairment. After 1988, funding for ambient biomonitoring was severely curtailed, resulting in the abandonment of routine ambient biomonitoring in the State.

In 1991, the bureau received numerous requests from the Office of Regulatory Policy to reactivate the Ambient Biomonitoring Network. The network stations have not been sampled since 1988 and a revisiting of the entire network was overdue. Long-term monitoring data from this network will be most beneficial to the generation of the 305(b) biennial report, to providing the department with the baseline data necessary to make sound environmental policy decisions in watershed management, and to direct permit activities.

Data Quality Objectives

Accordingly, in 1992 (fiscal year 93), the bureau designed and initiated the **Ambient Biomonitoring Network (AMNET)**. The goal of the program is to establish a network of lotic (running water) stations in each major watershed drainage basin (see Figure 1). Each watershed drainage basin will be biomonitoried for benthic macroinvertebrate populations on a five- to six-year rotation. The frequency of sampling is reflective of a realistic temporal lag between the cessation of a perturbation and a biological community's recovery from said perturbation. Experience in the 305(b) program, which reexamines the responses of N.J.'s biological communities to changes in water quality on a two-year cycle, has indicated that five years is the optimum frequency for long-term biomonitoring.

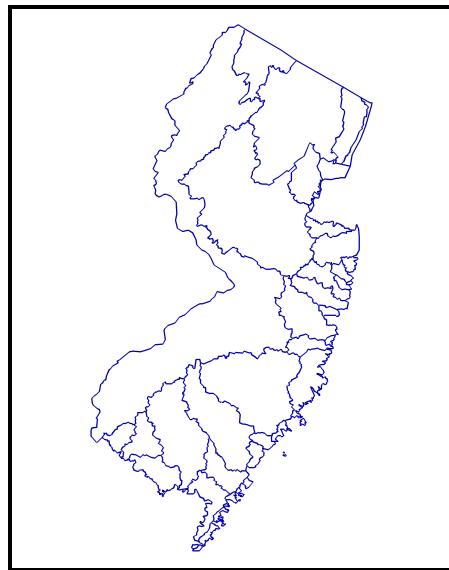

Figure 1 - Major Drainage Basins in N.J.

Based upon existing database deficiencies, the Arthur Kill (Rahway-Elizabeth rivers), Passaic, Hackensack, and Wallkill River Drainage Basins were selected to be monitored. The Rahway-Elizabeth Drainage Basin was sampled between Orange, Essex Co. and Rahway, Union Co. and between Irvington, Essex Co. and Union, Union Co. and Elizabeth, Union Co. The Passaic River Drainage Basin was sampled between Mendham Twp., Morris Co. and the mouth of Newark Bay, Newark, Essex Co. The Hackensack River Drainage Basin was sampled between Riverdale and South Hackensack, Bergen Co. The Wallkill Drainage Basin was sampled between Sparta and Wantage Twp., Sussex Co.

Site Selection

At least one monitoring station has been located on every second-order stream and all first-order streams at least three miles in length. Stream order is defined as a measure of the position of a stream in the hierarchy of tributaries. First-order streams are those with no tributaries, while second-order streams are those that have as tributaries only first-order streams.

To the greatest extent possible, the network incorporated existing USGS and NJDEP ambient monitoring stations so that correlation of the data sets could be maximized; for example, a dataset for stations sampled for a 1992 evaluation of the Upper Passaic River has been incorporated into this report. Furthermore, the network was designed with mainstem (second or third-order) stations located before the confluence of major tributaries and with stations located so as to assess the impacts of larger lakes. Known sources of contamination, and significant natural features (i.e., freshwater wetlands, preserves, FG&W Management Areas, etc.) were also considered when selecting the sampling locations. **Monitoring station locations in the study area are indicated on the G.I.S. Maps # 1 through 9.** All stations were positioned via the Global Positioning System, using Trimble Pathfinder Basic Plus global positioning units. Position data was corrected via the NJDEP and University of Rhode Island base station data sets. **Appendix A contains a compilation of all station locations as generated by the GPS.**

Since the objectives of this monitoring network are to provide long-term basin-wide biological impact data, the geographical dispersion of the stations was deemed adequate. However, it is likely that the monitoring resolution will not be sufficient to adequately assess the impact of any one point source of pollution. The development of site specific biological impact data is best handled by conducting an intensive biomonitoring survey.

While biological monitoring using benthic macroinvertebrate community structure is an excellent water quality monitoring tool, it is only one branch of water quality monitoring. Additional tools include water column chemistry, sediment chemistry, toxicity testing, fish tissue analysis, and fish community analysis. The most comprehensive evaluation would incorporate all of these elements. However, financial constraints make such monitoring difficult to perform. The frugality of benthic macroinvertebrate analysis provides the water pollution control professional with a holistic assessment of water quality at a reasonable cost.

Methods

Benthic Macroinvertebrate Sampling

The benthic macroinvertebrate sampling was performed in accordance with the procedures delineated in Chapter 7, section K. of the department's "Field Procedures Manual, NJDEP, May 1992" and, with the following modifications for application to New Jersey's waters, the USEPA's Rapid Bioassessment Protocol II as given in "U.S. Environmental Protection Agency (EPA), 1989, Rapid Bioassessment Protocols For Use In Streams and Rivers, EPA/4444/4-89-001, Assessment and Watershed Protection Division, Washington D.C." The rapid bioassessment was based upon an evaluation of relatively few samples collected at each station. AMNET's goal is to perform an evaluation of overall biological integrity by capitalizing upon the ability of benthic communities to holistically reflect environmental perturbations. It was imperative, therefore, that sampling be conducted when most of the benthic macroinvertebrates had both attained a size range likely to be retained during standard sieving and sorting, and when in a life stage most conducive to accurate identification. Since most emergence and reproduction occur in the spring and fall, a time when about 80 percent of the macroinvertebrates would be too small to be captured by conventional methods, the period between early June and early September was selected as the optimal collection period. In cases where fall emergence and reproduction were not an issue, sampling could continue into late fall / early winter.

Protocol II of the Rapid Bioassessment (RBPII) employs a systematic field collection of benthic macroinvertebrates and the subsequent analysis of the samples for major taxa. Semi-quantitative samples of benthic macroinvertebrates were collected from three different locations at each sampling station. Both riffle/run area samples and Coarse Particulate Organic Matter (CPOM) samples were included in a composite sample for a given station. Using composite samples ameliorates the effects of habitat inconsistency between stations. Samples were collected either with a Surber Sampler, Kick Net, Petite Ponar, or by hand picking. During the field investigation, qualitative observations of habitat, surrounding land use, obvious sources of pollution, and observations of other aquatic biota were made and recorded.

The entire sample collected was sieved through a #30 mesh sieve, put into an appropriate container, preserved with between 5% - 10% formalin (up to 20% formalin was used in cases of excessive organic loading), and transported to the bureau's biomonitoring laboratory for sorting and identification.

Sample Sorting and Identification

The samples were placed on a grid in a small pan with a light colored bottom for the sorting and enumeration of a 100 organism subsample, as per the protocol. The subsampling procedure consisted of evenly distributing the composite sample into the pan. Grids were randomly selected and all organisms within those grids were removed until 100 had been counted. All organisms in the subsample were identified to at least family, though in most cases the identifications were taken to the species level.

Data Analysis

Benthic community biological impairment may be manifested by the absence of

pollution-sensitive macroinvertebrate taxa (such as *Ephemeroptera* [mayfly], *Plecoptera* [stonefly], and *Trichoptera* [caddisfly]); by excessive dominance by certain taxon (especially pollution-tolerant groups such as some *Chironomidae* [midge] and *Oligochaeta* [aquatic worm]); by low overall taxa richness; or by perceptible shifts in community structure relative to a reference condition. All of these indicators were utilized in evaluating the RBPII sampling data generated during this study.

The RBPII data analysis protocol is a standardized bioassessment protocol developed by the USEPA in response to a need for a cost effective biomonitoring tool. The RBPII data analysis protocol integrates several community, population, and functional parameters into one easily comprehended evaluation of biological integrity. This integrated approach to data analysis recognizes that each parameter, or biometric, has different ranges of sensitivity to pollution stresses. An integrated assessment provides increased assurance of validity due to the variety of biometrics evaluated. A deficiency in any one metric for a particular environmental situation is, therefore, less likely to invalidate the study conclusions. The integrated assessment results in each station being given a biological condition category rating, providing the analyst with an easily communicated assessment of relative impairment; this assessment is referred to in this report as the **Bioassessment Rating**.

The USEPA RBPII data analysis protocol, with some revision, was utilized to evaluate the 1993 sample data. Sample station data was evaluated by comparison to a historical database, consisting of 200 benthic macroinvertebrate samples collected in the State, using the impairment criteria developed by Mr. J. Kurtenbach, USEPA - Region II (A Method for Rapid Bioassessment of Streams in New Jersey Using Benthic Macroinvertebrates, Annual Meeting of the North American Benthological Society, Santa Fe, 1991). The bioassessment scores resulting from said analyses are referred to as **NJ Impairment Scores (NJIS)**.

The biometrics used in the assessments are based on family level taxonomy. The NJIS was developed, using the aforementioned database, for evaluating New Jersey biomonitoring stations. Community metric criteria were established for three categories of water quality bioassessment; **non-impaired**, **moderately impaired**, and **severely impaired** (**Table 1**), using the following metrics: 1.) **Taxa Richness**, which reflects the health of a community through a measure of the total taxa; 2.) **E+P+T**; the total number of the intolerant forms: *Ephemeroptera*, *Plecoptera*, and *Tricoptera*; 3.) **%EPT** (including the hydropsychid family); 4.) **%Contribution of the Dominant Family (%CDF)**, a measure of community balance based upon the abundance of the numerically dominant taxon relative to the entire population; and 5.) **Modified Family Biotic Index (FBI)**, which summarizes FTV (Family Tolerance Values) into a single score reflective of organic pollution.

In addition to the metrics listed above, any abnormalities observed in chironomid detritovores, herbivores, and periphyton feeders, demonstrated by number of abnormalities per number of chironomids analyzed for abnormalities, were also used, qualitatively, when developing the final evaluation of biological impairment.

RESULTS and DISCUSSION

The bioassessment ratings developed for each of the monitoring stations were used as the basis for evaluating the degree of biological impairment in the stream segments. In each subbasin, starting from the most downstream station, estimated stream segment bioassessment ratings were assigned by interpolating from the downstream station to the next contiguous upstream station. The estimated stream segment bioassessment ratings are presented as color coded highlighted segments on each of the G.I.S. MAPS #'s 1 through 9. These ratings are best estimates of the instream biological impairment based upon the available data. For any given segment the actual instream conditions may be different due to unknown sources of degradation.

Overall, out of 113 monitoring stations sampled during this study period, 31.9% were rated as non-impaired, 54.9% were rated as moderately impaired, and 13.3% were rated as severely impaired (see Figure (2)).

When the Arthur Kill (Rahway-Elizabeth rivers), Passaic, Hackensack and Wallkill River Drainage Basins are examined by subbasin groupings, different patterns of biological impaired emerge. The Arthur Kill (Rahway-Elizabeth rivers) drainage is depicted in Figure 3.

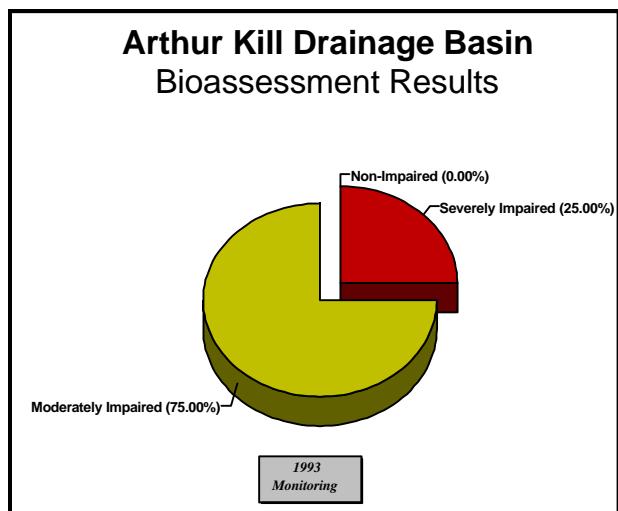

Figure 3

drainage is depicted in Figure 6. Most of the sites (71.4%) exhibited no impairment. The remaining sites (28.6%) were rated moderately impaired.

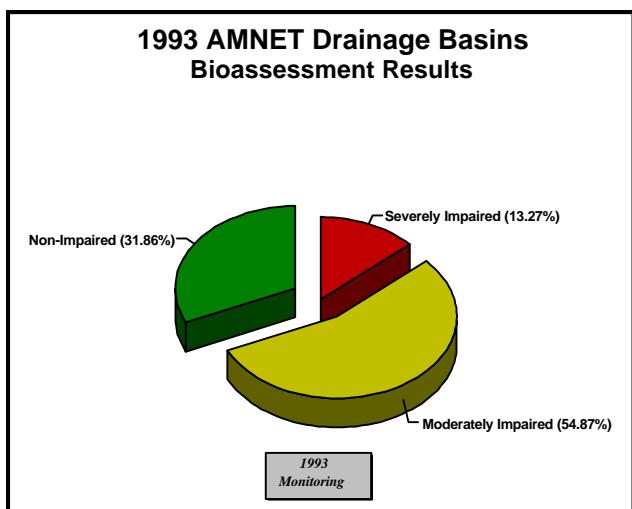

Figure 2

All sites exhibited impaired; 75% were categorized as moderately impaired. The remaining sites (25%) were rated severely impaired. The Passaic River drainage is depicted in Figure 4. No impairment was indicated at 32.1% of the sites. The majority of the sites (55.1%) exhibited moderate impairment; the remainder (12.8%) was severely impaired. The Hackensack River drainage is depicted in Figure 5. Non-impaired ratings were given to 11.1% of the sites. The majority of the sites (66.7%) exhibited a moderate degree of impairment. Severe impairment was indicated at the remaining (22.2%) sites. The Wallkill River

The raw taxonomic data, statistical analyses, and biological assessment ratings for each station are located in **Appendix B**.

WATER QUALITY IN NEW JERSEY STREAMS
Scoring Criteria For Rapid Bioassessments¹

Biometrics	6	3	0
1. Taxa Richness (total Families)	>10	10-5	4-0
2. E+P+T Index (EPT)	>5	5-3	2-0
3. Percent Dominance (%CDF)	<40	40-60	>60
4. Percent EPT ² (%EPT)	>35	35-10	<10
5. Modified Family Biotic Index ³ (FBI)	0-4	4-6	6-10

<u>Biological Assessment</u>	<u>Total Score</u>
Non-impaired	24-30
Moderately Impaired	9-21
Severely Impaired	0-6

Attributes

Non-impaired: Benthic community comparable to other undisturbed streams within the region. A community characterized by a maximum taxa richness, balanced taxa groups and good representation of intolerant individuals.

Moderately Impaired: Macroinvertebrate richness is reduced, in particular EPT taxa. Taxa composition changes result in reduced community balance and intolerant taxa become absent.

Severely Impaired: A dramatic change in the benthic community has occurred. Macroinvertebrates are dominated by a few taxa which are very abundant. Tolerant taxa are the only individuals present.

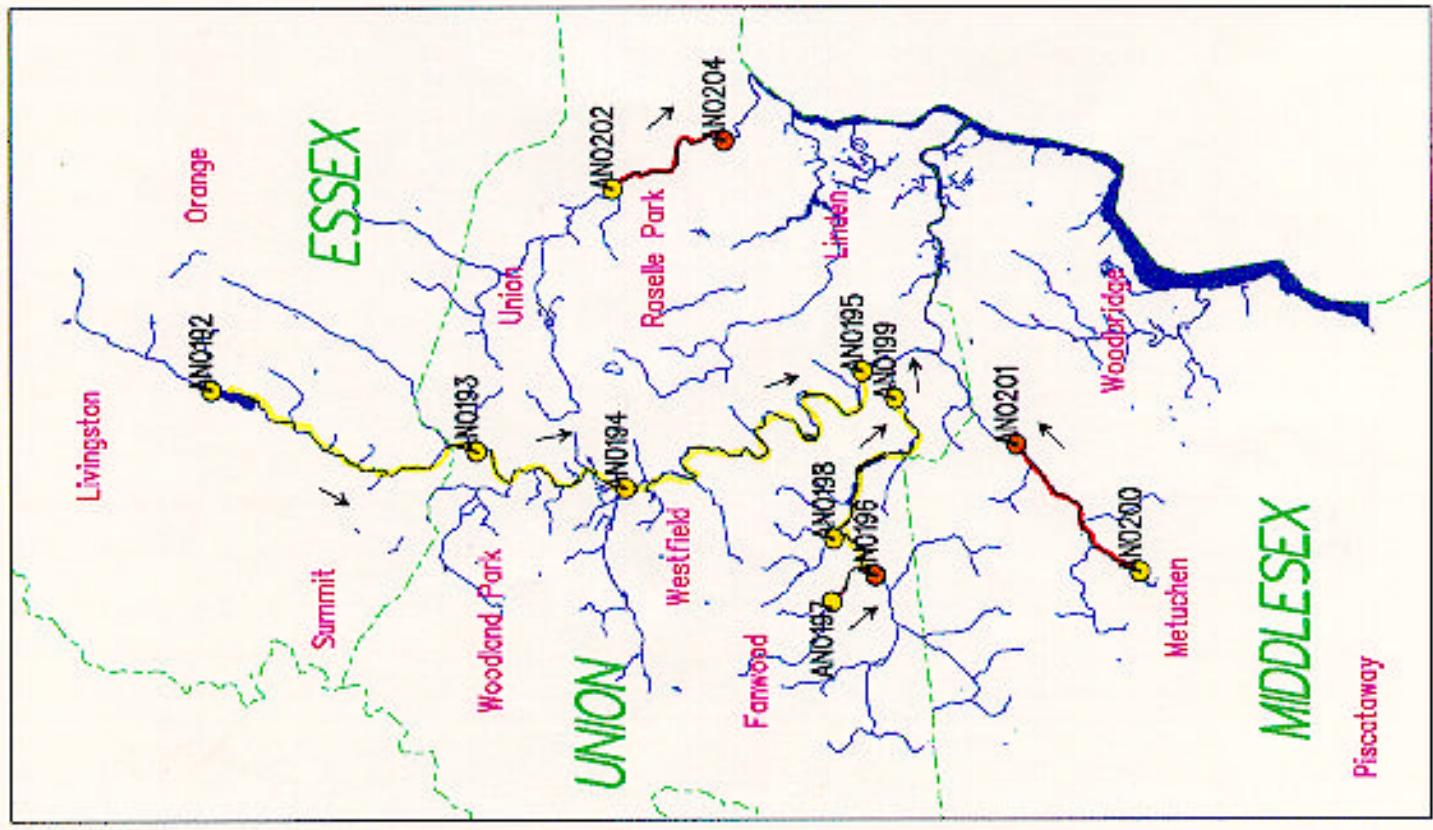

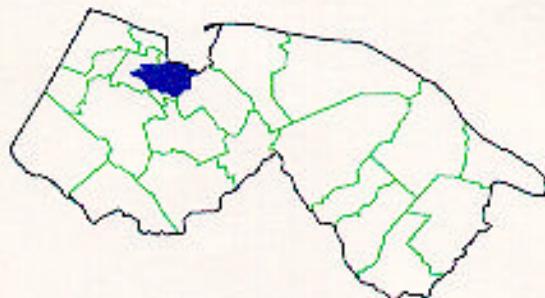

¹Based on 100 organism subsamples

²Including the hydropsychid family

³Also known as the Hilsenhoff Biotic Index
